Introduction

Late in 2004 I received a telephone call from Hélène Potter, director of new product development for Macmillan Reference USA—an imprint of Gale. I did not realize immediately that it was the telephone call that would shape a large share of my intellectual activity for the next three years. In fact, I recall hearing about a new edition of the *International Encyclopedia of the Social Sciences* (*IESS*), but I was wholly unclear about what was being asked of me. I asked Hélène, “So what exactly is it you want me to do? Prepare an article or two for the new edition?” Her response was, “No, no. We would like you to serve as editor of the new encyclopedia.” While vaguely glimpsing the labor that would be required to pull this off properly, but also realizing the importance of the project, I agreed.

I was aware of both the 1930–1935 *Encyclopaedia of the Social Sciences*, edited by E. R. A. Seligman and Alvin Johnson, and Macmillan’s 1968 *International Encyclopedia of the Social Sciences*, edited by David L. Sills, not only as key reference works of continuing value but also as vital expressions of the state of the social sciences (and the sociology of the social science community) at their respective historical moments. It would be an honor and a unique opportunity to play a key role in the development of the new encyclopedia that would assess the scope of the social sciences at the start of the twenty-first century.

From the outset, the decision was made to commission an entirely new set of articles for the second edition of *IESS*; no articles on overlapping topics from the previous edition would be reproduced in part or in whole. Instead, we would seek new voices and fresh perspectives for all of the entries. In fact, a few contributors even chose to make observations about entries from the previous edition in their articles.

The vision in assembling the new edition was to achieve comprehensiveness in coverage, to identify authors who would give their articles a critical edge and minimize hagiographic treatment of the leading figures in the fields represented, and to produce a set of volumes in which contested intellectual and ideological terrain is openly and honestly explored. Indeed, the new edition includes a variety of entries related to the philosophy of science that call into question what makes the study of the human “social” a “science” in the first place. Is it a matter of a particular set of practices, that is, variations on the “scientific method”? Is it a perspective or point of view that guides inquiry, that is, a detachment from practical or applied aims or a putative “objectivity”? Or is it something else altogether?
WHAT’S NEW IN THE NEW EDITION
The new edition reflects the impact of the rise of critical theory in its postmodernist forms on the social sciences, especially in the arenas of cultural anthropology, qualitative sociology, and methodology. Simultaneously, it includes the most sophisticated theoretical reaction to those developments—the reaction that has sublated those developments by challenging the nihilistic thrust of postmodernism—in the form of realist theory; the latter is not to be confused with “realism” or “realpolitik.” The new edition incorporates transformative developments in the social sciences: the routinization of the use of applied statistics and mathematical modeling in economics, psychology, and sociology; the rise of cultural studies, including the study of popular culture; the exploration of race, ethnicity, phenotype, and identity across the social sciences; the emergence of gender studies and women’s studies; the “coming out” of queer studies; the study of memory as something far more than a biomechanical act; and the recent construction and development of concepts like “the other,” Orientalism, causality, postcolonialism, the clash of civilizations, the gaze, marginalization, occupational crowding, generation X, and gentrification.

In addition, the new edition embodies the changing demographics of the academy. The 1968 IESS had an editorial advisory board consisting of more than 120 members. This was a highly distinguished group of scholars, a number of whom are profiled with biographical entries in the current IESS: Gordon Allport, Gabriel Almond, Kenneth B. Clark, Erik Erikson, E. E. Evans-Pritchard, E. Franklin Frazier, Morris Janowitz, Harold Lasswell, Paul Lazarsfeld, Claude Lévi-Strauss, W. Arthur Lewis, Margaret Mead, Robert K. Merton, Gunnar Myrdal, Talcott Parsons, Don Patinkin, Jean Piaget, Paul Samuelson, Herbert Simon, George Stigler, and Jan Tinbergen. Lewis, Samuelson, Simon, Stigler, and Tinbergen all became Nobel laureates in economics. But I count only three women—Mead, Hanna Rizk at the American University in Cairo, and Monica Wilson at the University of Cape Town—out of all of the members of the editorial advisory board.

By the late 1960s, the social sciences remained an overwhelmingly male preserve. Nevertheless, I was startled to find Alvin Johnson making the following remarks in his foreword to the 1968 IESS when discussing the genesis of the earlier Encyclopaedia of the Social Sciences:

It was not unnatural that Professor Seligman should ask me to examine the great commission he had undertaken as editor of the Encyclopaedia of the Social Sciences. He unfolded his plan—himself as editor, an associate editor, a copy editor (probably a depressed lady scholar), three or four secretaries, and a far-flung farming out of articles.

I loved E.R.A., and I hated to throw cold water on his ideas, but I had to say that this is no way to make a real encyclopedia. In the first place, articles should not be farmed out. Every article should be assigned to the man who is to sign it.

I was particularly startled by Johnson’s casual reference to “a depressed lady scholar”—who, if actually depressed, probably became so because of the professional discrimination she faced that assigned her to a position lower than the one she deserved—and the ease with which the assumption was made that the authors of articles would be men. Although we have not yet attained gender equity in the academy—indeed, it was still possible in 2005 to publish a volume titled The Origins of Law and Economics: Essays by the Founding Fathers—the current edition of IESS is richly alert to the contributions of female scholars in the social sciences.

We are much further from achieving racial equity in the academy, but, arguably, black scholars have made contributions that are disproportionate to their numerical presence in the social sciences. I believe those contributions are fully evident in the current IESS as well. Contributions from scholars from marginalized groups—the 1968 editorial advisory board included, at most, five black scholars—appear in the new edition through the regular process of identifying important developments in the social sciences. Their work is so central to ongoing scholarship across the social sciences that it can no longer be ignored, dismissed, or hidden from view.
EXPERT KNOWLEDGE, DEMOCRACY, AND THE ENCYCLOPEDIA

In his introduction to the 1968 edition, David Sills commented on:

[The] extent to which the social sciences have permeated society itself. It is not just that the vocabulary of the social sciences has infiltrated everyday speech, although it is common for persons with no formal training in the social sciences to use such terms as IQ, subculture, power structure, GNP, and the unconscious in their daily conversation. More important, many people today perceive the world differently because they have been exposed to the perspective of the social sciences; they raise their children differently; they have different attitudes toward government borrowing and spending; they make different judgments of their friends, neighbors, and family members; they view both local and national politics differently; they place a different and more sympathetic interpretation upon the guilt of criminals, drug addicts, and deviants of all kinds; and they make different judgments of their own successes and failures.

Sills’s observation is profound. Even on the narrower terrain of vocabulary, the array of terms and phrases that have migrated from the social sciences into popular discourse goes far beyond the brief list he offers: antisocial behavior, self-esteem, Type A or Type B personality, withdrawal symptoms, fixation, penis envy, anorexia, peer pressure, peer culture, inferiority complex, role model, sexual orientation, dysfunctional behavior, introvert and extrovert, conventional wisdom, permissiveness, schizo, hyper, klepto, self-fulfilling prophecy, interest groups, trickle-down, zero-sum game, karma, tough love, self-confidence, behavioral modification, catharsis, sociopath, phallic symbol, phobia, post-traumatic stress disorder, hallucination, blind spot, enabler, codependency, separation anxiety, Oedipus complex, passive-aggressive behavior, cognitive dissonance, obsessive-compulsive disorder (OCD), extrasensory perception (ESP), split personality, upward mobility, attention deficit disorder (ADD), narcissism, pathological liar, critical-thinking skills, déjà vu, closure, positive reinforcement, cultural norms, gender bias.

When concepts migrate they frequently undergo some change in meaning from the body of scholarship where they originated, and they may return to the social sciences under modified guise to be used by a new wave of scholars in a different way. Thus, there is an interdependence between “the experts’” culture and “the people’s” culture, a reciprocity that results in the reshaping of both as they interact. Indeed, we now have “the people’s” encyclopedia in the form of the online Wikipedia.

While I admire the democratizing aims of Wikipedia, IESS is a very different type of project—more informed by attachment to “the experts’” culture. We sought authors for the entries in the new edition who are specialists on the topics about which they were asked to write. In addition, we asked them to write in a style that will be accessible to a general audience, a readership of nonspecialists. That aim largely has been accomplished, with the exception of some of the articles that are devoted to more detailed, technical aspects of statistics and econometrics.

The entries in the second edition of IESS are final versions of the articles, and each is signed by its author or authors. We know who is responsible for what has been said; we know precisely who is responsible for arriving at a specific conclusion about a major controversy in the social sciences. Wikipedia has the advantage of having no deadlines (and no final versions since articles can be edited and updated indefinitely) and no limits to the topics that can be covered. It is not a social sciences encyclopedia per se—it is an encyclopedia of all human knowledge; even if it were a social sciences encyclopedia, there would be no boundaries on topics for consideration. My central complaint is the anonymity of authorship, which eliminates the ability to situate the perspective, the context, and possibly the motivation for the position taken by the author. It also eliminates the reader’s ability to assess whether the author really does possess sound knowledge about the topic.

Each summer I serve as an advisor to a group of talented students from schools across the United States who participate in the Moore Undergraduate Research Apprentice Pro-
gram at the University of North Carolina at Chapel Hill, a ten-week summer program where students tackle graduate-school-quality research projects of their own design. During the summer of 2007, I advised four students: Angela Perez, who worked on a project on black-Latino relations in post-Katrina New Orleans; Cory Edmonds, who did a critical examination of the A Better Chance program; Parfait Gasana, who did fresh work on James Duesenberry’s relative-income hypothesis in the context of consumerism literature; and Charnell Covert, who examined Zora Neale Hurston’s short stories. While Charnell was engaged in her project, we both took a look at the Wikipedia entry (last modified on August 31, 2007) on Hurston and discovered the following provocative passage:

During her prime, Hurston was a bootstrap Republican and fan of Booker T. Washington’s self-help and accommodationist politics. She was opposed to the collectivist visions (including communism) professed by many of her colleagues in the Harlem Renaissance, such as Langston Hughes, who wrote several poems in praise of the Soviet Union. Hurston thus became the leading black figure on the conservative Old Right, and in 1952 she actively promoted the presidential candidacy of Robert Taft, who was, like Hurston, opposed to integration.

Hurston opposed the Supreme Court ruling in the Brown v. Board of Education case of 1954. She felt the physical closeness of blacks to whites was not going to be the salvation her people hoped for, as she herself had had many experiences to the contrary. And she worried about the demise of black schools and black teachers as a way to pass on cultural tradition to future generations of African-Americans. She voiced this opposition in a letter, Court Order Can’t Make the Races Mix. The article then refers the reader to LewRockwell.com and the Marcus Epstein archives, where Hurston’s August 1955 letter to the Orlando Sentinel is reproduced.

Several questions arose for us: Was Hurston in fact a doyenne of the Old Right? Was she an antigovernment libertarian? Was she consistently hostile toward the New Deal in the United States, socialism in general, or the Soviet Union in particular? Were the issues she raised in her letter different or any less reasonable than those raised by W. E. B. Du Bois twenty years earlier in an essay called “Does the Negro Need Separate Schools?” published in the Journal of Negro Education? Or was the problem in Hurston’s case the sheer timing of her letter, coming immediately on the heels of the Brown decision? Who wrote this passage anyway? Was it Marcus Epstein? And, if so, who wrote the rest of the article on Hurston?

In contrast, consider the entry on Hurston in the current IESS by anthropologist Irma McClaurin. Most of the article is devoted to Hurston’s role as folklorist and ethnologist of African American and southern culture. McClaurin does not take a fixed position on Hurston’s politico-ideological orientation because, from McClaurin’s perspective, that is a question that remains unresolved on the basis of the available evidence.

Closer in intent and philosophy to the second IESS is the International Encyclopedia of the Social and Behavioral Sciences (2001) edited by Neil Smelser and Paul Baltes. This extensive, high-quality reference work also is predicated on “the experts” culture dictating the content of the encyclopedia. One difference between IESS and the Smelser-Baltes encyclopedia is that the authors who contributed to the IESS were actively encouraged to highlight central fissures, disagreements, and controversies that have arisen in the social sciences, including disputes that have arisen over the interpretation of important historical figures’ lives and the interpretation of important historical events. There is a difference, then, in perspective and content.

There is also a difference between IESS and the Smelser-Baltes encyclopedia in the range of topics treated. The new edition of IESS allots greater emphasis to the impact of critical theory, cultural studies, and the mathematicization of empirical research on the social sciences. This leads, in turn, to a remarkably eclectic mix of articles in IESS that ranges from Logistic Regression to Racial Slurs to Hip Hop to Cholesky Decomposition to the Linguistic Turn to Fixed Effects Regression to Labeling Theory to the Wizard of Oz.
THE COMMUNITY OF CONTRIBUTORS TO THE SECOND IESS

There are more than 2,100 (nonanonymous) authors of close to 3,000 entries for the new edition of IESS. And what an impressive array of scholars have written the articles! Economics Nobel laureates Paul Samuelson and Robert Solow unknowingly wrote biographies on one another. Solow also wrote the biography on Nobel laureate Lawrence Klein, who, in turn, wrote the biographies on Nobel laureates Ragnar Frisch and Jan Tinbergen. Klein is one of a small number of distinguished scholars who contributed articles to both the previous edition of IESS and the new edition. The others include Terry N. Clark, Philip E. Converse, Richard G. Lipsey, Stanley G. Payne, Thomas F. Pettigrew, and Edward A. Tiryakian.

The close relationship between expertise, authoritativeness, and authorship in the second IESS is well illustrated by a slight sample: James Flynn (and there is a separate entry on the Flynn Effect by Matthew Scullin) writes about the IQ controversy, Kay Schlozman writes about political inequality, Burton Malkiel writes about the random walk, Jerry Hausman and Hal White write about Hausman tests, Joseph Inikori writes about the slave-gun cycle that emerged during the course of the Atlantic slave trade, Carol Graham writes about research on happiness, Jonathan Boyarin writes about the history of Jewish peoples, Faye Harrison writes about race and the field of anthropology, and Gananath Obeyesekere writes about reincarnation. This is only a tiny subset of the luminaries who wrote articles for the new edition of the International Encyclopedia of the Social Sciences. Numerous authors wrote multiple articles. Those who contributed ten or more entries include David Embrick, Mathew Forstater, Galina Hale, Dudley Poston Jr., Lall Ramrattan, Sean Savage, Michael Szenberg, Bryan S. Turner, and Rossen Vassilev. Without their extraordinary efforts the new edition would not have the depth and quality that it enjoys.

Because of deadlines, limitations on space, and the inability to find authors for every topic that the editorial team deemed worthy of coverage, there are some omissions from the current IESS. While, typically, the following scholars make appearances throughout the articles in the new edition, it would have been desirable to have full biographical articles on: Arjun Appadurai, Ruth Behar, David Blackwell, E. A. Boateng, Kenneth Boulding, Hollis Chenery, James S. Coleman, Philip Converse, Louis Dumont, Richard Easterlin, Alvin Gouldner, Harold Hotelling, Nicholas Kaldor, Simon Kuznets, Jacques Lacan, Steven Lukes, Mahmood Mamdani, Robert C. Merton, Daniel Pipes, Myron Scholes, Henri Theil, James Q. Wilson, and Harriet Zuckerman. IESS also could have benefited from separate entries on such topics as cultural determinism, reality television, the punk rock movement, and Harry Potter, as well as entries that directly explored the spectacular rise of Jewish scholars in the American and British universities from the 1930s onward and the persistent exclusion of women from the mathematical and statistical sciences.

Those omissions aside, I find myself astonished at the magnitude of the material that is covered—and covered at such a high level of quality—in the current IESS. For this to occur, the new edition required a fantastic team of associate editors, who are major scholars in the social sciences in their own right, and an outstanding editorial staff at Macmillan/Gale. I had the great fortune to have the following persons consent to serve as associate editors: Eduardo Bonilla-Silva (sociology), Philip Costanzo (psychology), Patrick Mason (economics), Paula McClain (political science), Donald Nonini (anthropology), David Scott (anthropology), and Theresa Singleton (anthropology). They, in turn, brought on board a trio of consulting editors who made signal contributions to the completion of the encyclopedia: David Dietrich (sociology), J. Alan Kendrick (political science), and Ley Killeya-Jones (psychology). I also wish to extend a special thanks to Robert Dimand and Michael S. Lawlor for suggesting fine author candidates for a number of important economics articles.

While Hélène Potter maintained supportive and wise supervision of the process, I must give special mention to the efforts of Alan Hedblad and Shawn Corridor at Macmillan in bringing the new edition to fruition. Alan, in particular, worked to the finish on the encyclopedia, guiding the process of communication with the authors of the articles (the authors...
are the lifeblood of any encyclopedia), managing deadlines, identifying the shifting priorities in tasks to be accomplished, and generally maintaining good spirits in the midst of a high-pressure production with hard deadlines.

I also thank my wife, Kirsten Mullen, and my sons, Aden Darity (who contributed the article *Bamboozled* to the new edition) and William O. Darity, for their love and support during the long process of preparing *IESS*. They shepherded me through recovery from major surgery in the fall of 2005 when, I suspect, the staff at Macmillan was probably concerned that they might actually lose an editor. Kirsten, a folklorist, occasionally made great suggestions about potential contributors and articles, and she helped me assemble the list of terms that have made their way from academic social science into popular discourse.

This has been an adventure of the mind and spirit. I hope that readers of the encyclopedia will find in it the value that those of us who have worked on the set have seen in it during the act of preparation.

The following classification of articles, arranged thematically, gives an overview of the variety of entries and the breadth of subjects treated in the encyclopedia. Along with the index in volume 9 and the alphabetical arrangement of all entries, the thematic outline should aid in the location of topics. Ideally, this feature will facilitate a kind of browsing that invites the reader to discover additional articles, related perhaps tangentially to those originally sought. Because the rubrics used as section headings are not mutually exclusive, certain entries in the Encyclopedia are listed in more than one section below.

1. Anthropology
2. Archaeology
3. Arts, Media, and Popular Culture
4. Demography
5. Econometrics
6. Economic Development
7. Economics
8. Education
9. Geography
10. History and Historiography
11. Interdisciplinary Studies
12. International Relations, Organization, and Law
13. Law
14. Linguistics
15. Methodology
16. Personality
17. Philosophy of Science
18. Political Science
19. Professions
20. Psychiatry
21. Psychology, Applied
22. Psychology, General
23. Religion
24. Social Issues and Policy
25. Social Psychology
26. Social Sciences
27. Societies
28. Sociology

ABORTION
Induced abortion, in contrast to spontaneous abortion, is the deliberate termination of an established pregnancy. Induced abortion is a universal phenomenon, present in every known culture—literate or preliterate, primitive or modern. What has differed has been the safety of the methods used; how widespread the practice has been, especially relative to contraception and infanticide; and the role of church and state.

Induced abortion was certainly practiced in ancient societies. The oldest known recipe for abortifacients comes from an ancient Egyptian papyrus dating back to 1550 BCE, which lists substances that terminate pregnancy in the first, second, and third trimesters. Ancient Greeks also used herbal abortifacients, including silphium (a giant fennel), pennyroyal, and myrrh; modern analyses suggest that many of these were effective. Abortion was common in both ancient Greece and Rome, although not nearly as widespread as infanticide. The timing of animation or ensoulment was of great interest to Greek philosophers. Aristotle (384–322 BCE) hypothesized that the fetus had a succession of souls: vegetable, animal, and rational. He also believed that animation occurred in the male fetus forty days after conception and in the female fetus after eighty days. Among Romans, the prevailing view was that the fetus became a person, an entity with a soul, only at the time it began to breathe.

Abortion practices varied widely among early Christians, who generally believed that fetuses did not have a soul until sometime after conception. Saint Augustine (354–430 CE) accepted Aristotle’s theory of delayed animation of the female fetus and contributed his own description of fetal development: the first six days in milky form, nine more days for it to turn to blood, twelve days for the mass of blood to solidify, and eighteen more days for the mass to become fully formed with all of its members.
Abortion

During the Middle Ages, a woman was considered to have had an abortion only if a formed fetus was extracted. Abortion among Christians remained a local issue, and penalties imposed for procuring abortions varied widely among localities. In the thirteenth century, the Christian philosopher Thomas Aquinas (c. 1225–1274) expanded upon the ideas of his predecessors, accepting Aristotle’s view that male semen alone had the power of creation. He reasoned that since beings tend to reproduce their own kind, the products of conception ordinarily would be male. Females must result from flaws in the semen or an act of God, such as the south wind. Aquinas’s ideas influenced Pope Innocent IV (d. 1254), who declared that abortion before the infusion of the soul was not homicide.

The papal position did not change again for three centuries. In 1588 Pope Sixtus V (1521–1590) declared that whoever practiced abortion, which he believed to be premeditated murder, was to be excommunicated and put to death. In 1591 Pope Gregory XIV (1535–1591) withdrew these penalties for the sin of abortion, which he believed were too severe in light of the debate on animation or ensoulment. This remained the Catholic Church’s abortion policy until 1869, when Pope Pius IX (1792–1878) restored Sixtus V’s declaration, thus eliminating any distinction between an animated and an unanimated fetus.

Despite its change in doctrine, the Catholic Church did not play an important role in the passage of antiabortion legislation in either England or the United States during the nineteenth century. At the beginning of the nineteenth century, English common law, which also applied in the United States, allowed induced abortion until at least quickening, that is, when the woman first feels fetal movements, usually between the fourth and fifth months of pregnancy. The change in British law occurred in 1803 when induced abortion was made illegal throughout pregnancy. The change in American law occurred somewhat later through two waves of state antiabortion legislation.

The first wave occurred between 1821 and 1841. Ten states and one territory enacted legislation to make some abortions illegal. Connecticut passed the first statute in 1821, prohibiting the administration of poisons to produce postquickening abortions. In 1828 New York banned postquickening abortions by all methods. Other than politicians and physicians, there was little popular support for these laws, and they were almost never enforced.

Massachusetts launched the second wave of antiabortion legislation in 1846 with a law that ignored the notion of quickening and included jail sentences and fines for attempted abortions. New York followed suit in the same year and passed an abortion law that also disregarded quickening and prescribed punishments for abortionists and abortion patients. Between 1840 and 1880, forty antiabortion state laws were passed. By 1910 induced abortion at any stage was a criminal offense in every state except Kentucky. The only exception was a therapeutic abortion, performed to save the pregnant woman’s life. However stringent, these state laws were ineffective in curtailing abortions—reliable estimates show that abortion rates climbed throughout the nineteenth century.

During the first half of the twentieth century, an estimated one in three pregnancies ended in abortion. Most of these abortions were illegal and unregulated, resulting in high morbidity and mortality rates for poor and rural women. The rationale for therapeutic abortions had also expanded over time. For women who had access to physician services, induced abortions became relatively safe by the mid-twentieth century. Not surprisingly, the medical profession became a principal advocate for reforming the antiabortion laws for which it had lobbied in the previous century.

Abortion was legalized in the United Kingdom in 1967 and throughout the United States in 1973. While these policy changes occurred within about five years of each other, their paths were almost totally divergent. In Britain, the law was liberalized after a fierce political campaign. In the United States, abortion reform occurred judicially rather than through legislative deliberation. In both counties, deaths from abortions plummeted after the abortion laws were liberalized, but these reformed policies have not settled the abortion debate in either country. However, abortion politics have been far more contentious in the United States than in the United Kingdom.

In 1973 the U.S. Supreme Court’s decision in Roe v. Wade overturned existing state laws by holding that a woman’s right to choose abortion was constitutionally protected as part of her right to privacy. This decision prohibited any level of government from interfering with a woman’s right to obtain an abortion during the first trimester except to require that it be performed by a licensed physician. During the second trimester, the state had only the power to regulate abortion in ways designed to preserve and protect the woman’s health. In the third trimester, the protection of fetal life became a compelling reason to justify state interference with a woman’s right to obtain an abortion. Beyond these broad parameters, individual states were free to regulate other aspects of abortion.

By permitting considerable state discretion, Roe v. Wade federalized, rather than nationalized, abortion policy. Consequently, state abortion laws differ widely in terms of parental involvement, informed consent, and funding for poor women. Since Roe, the U.S. Supreme
Court has decided over thirty abortion-related cases emanating from the states. The changing composition of the Court has meant that American abortion case law has changed over time.

A key question that remained in the early twenty-first century was whether the U.S. Supreme Court would overturn the Roe decision. Such a decision would have serious ramifications. In the 2000s, about one in three women in the United States had an abortion by the age of forty-five.

ABORTION RIGHTS

Abortion (also known as induced abortion, to distinguish it from miscarriage) is the intentional termination of a pregnancy prior to the time when the embryo or fetus is viable. Abortion rights refers to the claim that abortion is a liberty that is or ought to be protected by law.

INTERNATIONAL ABORTION LAWS

Internationally, abortion is legal for about two-thirds of the world’s population. Abortion laws vary widely. Abortion in some countries is available on demand (for any reason) throughout part or all of pregnancy. In some countries it is illegal under all circumstances. Some countries take a middle path in which access to abortion is regulated but not prohibited. In these countries legal restrictions, along with the seriousness of the reasons necessary for permitting an abortion, tend to increase along with the gestational age of the fetus. The reasons for permitting abortion may include maternal life and health (sometimes including mental health), pregnancy resulting from rape, social and economic factors, and defects in the fetus.

ABORTION LAWS IN THE UNITED STATES

In the United States, prior to the nineteenth century, early abortion was largely unregulated. Common law considered abortion at most a misdemeanor if it occurred prior to quickening (the perception of movement in the fetus, generally in the fourth month of pregnancy). Termination of early pregnancy was commonly spoken of as not as abortion but as restoration of blocked menstruation, which could be accomplished by taking abortifacient herbs or drugs or by mechanical means. Between 1820 and 1900, however, laws were passed by every state prohibiting abortion at any stage of pregnancy, except to save the life of the pregnant woman. The American Medical Association (AMA) advocated for restrictive abortion laws on the grounds that pregnancy was a continuous process, that quickening was not a true indicator of the beginning of fetal life, and that to end fetal life through abortion was unethical unless the pregnant woman’s life was endangered.

During the period in which abortion was illegal, it was still practiced, whether outside the law or by physicians acting within the law (sometimes broadly interpreted). Public concern with the issue of abortion increased in response to the well-publicized case of Sherri Finkbine, an Arizona woman who sought an abortion in 1962 after taking thalidomide (a drug known to cause serious birth defects) during her pregnancy. From 1962 to 1965, the birth of thousands of babies with birth defects following a rubella outbreak further contributed to public concern. By 1973 eighteen states, with the support of the AMA, had adopted less restrictive abortion laws. However, in the late 1960s and early 1970s abortion came to be identified as primarily a women’s issue rather than a medical issue as it had been in the past. Women’s groups such as the National Organization for Women (NOW) and the National Association for the Repeal of Abortion Laws (NARAL) were founded. These and other groups identified abortion as a right of women and called for the repeal, rather than the reform, of abortion laws.
ROE V. WADE (1973)

In 1973 the U.S. Supreme Court handed down opinions in two cases, Roe v. Wade (an appeal of a case filed in Texas) and Doe v. Bolton (a Georgia case). The majority opinion held that the right of privacy that exists in the Constitution (often attributed to the Ninth and Fourteenth Amendments) “is broad enough to encompass a woman’s decision whether or not to terminate her pregnancy” (Section VIII). The court held that the right to an abortion is not absolute, meaning that it can be justifiably infringed for the sake of other interests such as those in “safeguarding health, in maintaining medical standards, and in protecting potential life” (Section VIII). The opinion held, importantly, that the word “person” in the Fourteenth Amendment did not “include the unborn” (Section IX). On the basis of these principles, the justices set up a framework for abortion laws in which each trimester (third) of pregnancy could be treated somewhat differently. In the first trimester, no state interference with abortion would be permitted. Beginning in the second, the states could regulate abortion for the sake of protecting the health of the pregnant woman, and at the point of fetal viability, the states could enact legislation designed to protect the life of the fetus, except when abortion was necessary to protect the pregnant woman’s life or health.

AFTER ROE V. WADE

This landmark decision was celebrated by supporters of the repeal of abortion laws (pro-choice groups) and decried by groups who were pro-life (those in favor of restrictive abortion laws, such as the National Right to Life Committee). At the state level, between 1973 and 1989 several hundred laws were passed to regulate abortion, for example by allowing a spouse or parent to overrule the pregnant woman’s abortion decision, requiring twenty-four-hour waiting periods, or by enacting other restrictions. Many of these laws were challenged and rejected because they did not accord with the framework set forth in Roe. Other laws, such as a requirement of parental notification for dependent minors, were upheld. In Webster v. Reproductive Health Services (1989), the Supreme Court seemed ready to reject Roe when it upheld a Missouri law that declared that human life began at conception and that required second-trimester tests of the fetus for viability. The decision referred to the trimester framework of Roe as “rigid” and “unworkable” (Devins 1996, p. 66). However, in Planned Parenthood of Southeastern Pennsylvania v. Casey (1992), the court affirmed the central principles of Roe, including “recognition of the right of the woman to choose to have an abortion before viability and to obtain it without undue interference from the State” (Section I). The court rejected the trimester framework, adopting instead the standard of an undue burden and stating, “[a]n undue burden exists, and therefore a provision of law is invalid, if its purpose or effect is to place a substantial obstacle in the path of a woman seeking an abortion before the fetus attains viability” (Section IV).

In addition to challenges from state legislatures, other challenges to (and affirmations of) the Roe framework came from members of Congress and from the executive branch. The Hyde Amendment to a 1976 Department of Health, Education, and Welfare appropriations bill resulted in an end to Medicaid funding for abortion. Congress considered several proposals that would have either affirmed or overturned the basic principles of Roe, but did not adopt any of them. Congress also used its oversight of federal judicial appointments as an occasion to question candidates concerning their views of abortion rights. Particular issues that have galvanized debate in the years following Roe have included that of late-term abortion and of the contraceptive RU-486, sometimes called the abortion pill.

Ethical debates concerning abortion turn on the questions of whether the fetus should be regarded as a human being with rights (and if so, at what point in its development it acquires these rights), as well as the extent to which a pregnant woman has a moral obligation to bring a fetus to term, even if doing so requires that her own interests be compromised or sacrificed. Depending on the answers to these questions, abortion may be viewed as primarily an individual woman’s right, or as an area in which some degree of state regulation is warranted.

ABSOLUTE AND COMPARATIVE ADVANTAGE

During the seventeenth and eighteenth centuries the dominant economic philosophy was mercantilism, which advocated severe restrictions on import and aggressive efforts to increase export. The resulting export surplus was supposed to enrich the nation through the inflow of precious metals. Adam Smith (1776), who is regarded as the father of modern economics, countered mercantilist ideas by developing the concept of absolute advantage. He argued that it was impossible for all nations to become rich simultaneously by following mercantilist prescriptions because the export of one nation is another nation’s import. However, all nations would gain simultaneously if they practiced free trade and specialized in accordance with their absolute advantage. Table I, illustrating Smith’s concept of absolute advantage, shows quantities of wheat and cloth produced by one hour’s work in two countries, the United States and the United Kingdom.

Division of labor and specialization occupy a central place in Smith’s writing. Table I indicates what the international division of labor should be, as the United States has an absolute advantage in wheat and the U.K. has an absolute advantage in cloth. Smith’s absolute advantage is determined by a simple comparison of labor productivities across countries. Smith’s theory of absolute advantage predicts that the United States will produce only wheat (W) and the U.K. will produce only cloth (C). Both nations would gain if they have unrestricted trade in wheat and cloth. If they trade 6W for 6C, then the gain of the United States is 1/2 hour’s work, which is required to produce the extra 2C that it is getting through trade with the U.K. Because the U.K. stops wheat production, the 6W it gets from the United States will save six hours of labor time with which 30C can be produced. After exchanging 6C out of 30C, the U.K. is left with 24C, which is equivalent to almost five hours’ labor time. Nations can produce more quantities of goods in which they have absolute advantage with the labor time they save through international trade.

Though Smith successfully established the case for free trade, he did not develop the concept of comparative advantage. Because absolute advantage is determined by a simple comparison of labor productivities, it is possible for a nation to have absolute advantage in nothing. In Table I, if the labor productivity in cloth production in the United States happened to be 8 instead of 4, then the United States would have absolute advantage in both goods and the U.K. would have absolute advantage in neither. Adam Smith, however, was much more concerned with the role of foreign trade in economic development and his model was essentially a dynamic one with variable factor supplies, as pointed out by Hla Myint (1977). David Ricardo (1817) was concerned with the static resource allocation problem when he defined the concept of comparative advantage, which is determined not by absolute values of labor productivity but by labor productivity ratios. Ricardo would have interpreted the numbers in Table I by pointing out that, whereas U.S. labor in wheat production is 1.5 (= 6/4) times as productive as it is in cloth production, the U.K.’s labor productivity in wheat is only one fifth of its labor productivity in cloth. Therefore, the United States has comparative advantage in wheat and by inverting these ratios one can show that the U.K. has comparative advantage in cloth. This pattern of comparative advantage will not be affected if the United States has absolute advantage in both wheat and cloth, which will be the case if we raise U.S. labor productivity in cloth from 4 to 8. This is because 3/4 will still be greater than 1/5.

The rationale of labor productivity ratios comes from Ricardo’s labor theory of value. Ricardo treated labor as the only source of value, as all other factors of production (such as capital) are also produced by labor. Thus the price of a good (P) is simply equal to the wage rate (w) times the labor (L) used in production, divided by output (Q), as profit is zero in competitive markets: P = (wL)/Q. Because the average productivity of labor is a = Q / L, P = w / a. If the labor market is competitive, the wage rate paid in all industries will be the same. Therefore, the ratio between the price of wheat (Pw) and the price of cloth (Pc) will be equal to the ratio between average productivity of labor in cloth (ac) and average productivity of labor in wheat (aw): [Pw / Pc] = [ac / aw]. This creates a direct link between comparative advantage and relative commodity prices in a competitive economy. If the United States has comparative advantage in wheat production, wheat will be relatively cheaper in the United States than in the U.K., which provides the basis for trade.

Ricardo’s theory of comparative advantage creates hope for technologically backward countries by implying that they can be a part of the world trading system even though their labor productivity in every good may be lower than that in the developed countries. In the Ricardian model, trade is a win-win situation, as workers
in all trading countries are able to consume more of all goods. Ricardo was blissfully unaware of the complications that would be created if his model included another factor such as capital, and if the producers had responded to changes in factor price ratio in favor of the cheaper factor. It was Wolfgang Stolper and Paul A. Samuelson (1941) who later discussed the effect of international trade on income distribution. The comparative advantage model has many unrealistic assumptions, which ignore the fact that the real world consists of many countries producing many goods using many factors of production. Each market is assumed to be perfectly competitive, when in reality there are many industries in which firms have market power. Labor productivity is assumed to be fixed and full employment is guaranteed. The model assumes that technology differences are the only differences that exist between the countries. Finally, in a dynamic context, comparative advantage changes, as trade in goods and capital alters the trading countries’ factor endowments. Hajime Oniki and Hirofumi Uzawa (1965) have shown in a formal model how trade and economic growth continuously change patterns of trade and specialization.

In spite of its shortcomings, some of which have been removed by subsequent research (see Chipman 1965–1966), Ricardo’s model carries a message that cannot be ignored. Ricardo’s most important contribution lies in the fact that he was the first economist to link specialization with opportunity cost, which is the basis of modern trade theory. As for empirical testing of Ricardo’s theories, G. D. A. MacDougall (1951–1952) demonstrated that trade between the United States and the U.K. in 1937 followed Ricardo’s prediction. As a matter of fact, Ricardian theory performs better in empirical testing than most other theories.

**ABSOLUTE INCOME HYPOTHESIS**

The consumption function, a key behavioral relationship in macroeconomics, was first introduced by John Maynard Keynes (1883–1946) in 1936. While Keynes offered no precise functional formulation of the propensity to consume (in his original terminology), his analysis has come to be associated with a simple version of the consumption function that embodies only the more quantitative aspects of his considerations, popularly known as the simple Keynesian consumption function or absolute income hypothesis (AIH).

The AIH is readily described using four propositions expressed in terms of the marginal propensity to consume (MPC) and the average propensity to consume (APC), where the MPC is the change in real consumption ($c$) for a unit change in real disposable (after-tax) income ($y$), and the APC is the ratio of consumption to real disposable income:

1. That real consumption is a stable function of real disposable income.
2. That the MPC is a positive fraction.
3. That the MPC is less than the APC, and the APC declines as income rises.
4. That the MPC declines as income rises.

The most common representation of the AIH is the linear function (inclusive of an intercept) that satisfies (1), (2), and (3), but not (4) (see Figure 1). Such a simple linear consumption function is to be found in nearly all introductory macroeconomic textbooks.

While early empirical work found support for the AIH and the proposition that the APC falls as income rises, long-run data offered contrary evidence (Kuznets 1946). This indicated that the APC out of national disposable income appeared not to vary with rising income over the relatively long run; in particular, it did not fall as
disposable income rose, as predicted by the linear AIH inclusive of an intercept. Rather, the apparent constancy of the APC suggested a long-run proportional consumption function (C), such that the APC equals the MPC. In contrast, the examination of household budget data (Brady and Friedman 1947) revealed the cross-section consumption function to have a positive intercept, and a lower MPC than APC in any given year (B). The dilemma therefore arose of how to reconcile the long-run proportional consumption function with the finding from short-run and cross-section analyses that the APC exceeded the MPC.

It should also be noted that the AIH predicts a simple positive relationship between consumption and income, such that the two should not move in opposite directions, nor one change and not the other. However, data shows the two variables disobey this suggested relationship, the most prevalent of such irregularities involving an increase in consumption with a decrease in income, which the AIH is unable to account for. Moreover, the AIH consistently underpredicted consumption for the mid-twentieth century. The is partly explained by noting that during and immediately following World War II (1939–1945), increases in income could not be translated into increased expenditure due to rationing, forced holdings of liquid assets being subsequently converted into increased consumption demand following the relaxation of rationing. Such reasoning suggests that assets, and thereby wealth, may be a significant consumption determinant, and gave rise to modern theories of consumption, such as the life-cycle hypothesis (Modigliani and Brumberg 1955; Ando and Modigliani 1963) and the permanent income hypothesis (Friedman 1957), which emphasize the role of wealth and other factors in explaining the paradoxes noted above.

ACCIDENTS, INDUSTRIAL

The term industrial accidents refers to events involving unintended injury, harm, or damage that occur unexpectedly in the process of industrial production.

Definitions of what an accident is and theories concerning industrial accidents have evolved over time, and have differed depending on social context. Preindustrial workplaces were largely unregulated by the state. Tom Dwyer (1991) analyzed accidents in the preindustrial workplace and noted their regulation via moral practice, with Christian notions of “sin” being used to label and control the workplace. As the Industrial Revolution emerged in the United States and Europe, however, so too did new ideas about the worker and the workplace, along with an increased role for the state, rather than small groups and the individual, in defining accidents and addressing the concerns they generated.

The British coal mining industry provides a useful encapsulation of Anglo-American ideas regarding the treatment of industrial accidents in the nineteenth and twentieth centuries. Reports of British mining accidents begin to appear in the early nineteenth century (from 1812 onward), and demonstrate the social value placed on the prevention of industrial accidents. As labor unions emerged, European and American societies also came to expect the state to address concerns about deplorable working conditions in mines and large-scale industrial factories. Workers’ grievances regarding accidents were addressed to some extent through the gradual introduction of state regulation. The frequency of accidents, and their pattern and types, reflected the conflict between labor and capital that existed in larger society, as well as the evolution of technology (Dwyer 1991).

Despite the introduction of regulation, life for the typical European or American industrial worker in the late nineteenth and early twentieth centuries was abysmal. Upton Sinclair’s The Jungle (1906) is often credited with raising consciousness about problems in the industrial workplace, such as long work hours, grotesque injuries, the inability to file complaints and report accidents, and economic exploitation. The American progressive movement brought some of these issues into the political realm, though only the most severe problems were actually corrected during the early twentieth century.

The workers’ movement created a new emphasis on the prevention of accidents, leading to state regulations that codified types of violation. Labor unions pressed for safety changes to reduce the incidence of accidental injuries. At the same time, the technology of the industrial workplace became highly specialized. Early workplace safety procedures made use of this increasing specialization of labor, by allowing the worker, for instance, to stop the assembly line and halt production when safety was at risk. New laws were also used to regulate lost time, lost production of goods, damaged or broken equipment, and worker claims against industrial firms. These laws generally favored the financial interests of owners and paralleled the movement toward bureaucratization of management and the workplace.

Industrialization bloomed in the United States and Western Europe in the late nineteenth and early twentieth centuries. So too did social science. The work of Frederic Taylor and the theories of Scientific Management suggested that owners of factories benefited from dividing labor into specialized jobs—that is, it was more productive to divide work into separate, repetitive jobs that could be understood and controlled on the basis of time studies. Ford’s use of the assembly line created a highly specialized and linear form of production that set the model for many Western organizations. Accidents, also, came to be viewed as somewhat predictable and thus controllable, with models for prevention arising in response.

Max Weber’s work analyzed the ways in which legal/rational authority was used by owners to create a new managerial class that separated owners from workers. A new salaried middle class of managers emerged, with little or no ownership of the industrial factories and firms they managed. The modern corporation shifted responsibility for the day-to-day operations of industrial organizations away from owners to managers. Management became highly specialized as well, with the separation of “thinkers” from “doers” in Scientific Management underlying this division.

Large industrial organizations instituted the complex division of labor into multiple layers of linear production (e.g., the assembly line) and other nonlinear divisions. At the same time, arguably, accidents became less visible, and workers’ grievances became internalized within the structures of the organization of production, rather than being dealt with by the state (Dwyer 1991). In the United States, this created a counter-response from labor unions, which began advocating for more state regulation.

The creation of the Office of Safety and Health Administration (OSHA) in 1970, as an agency of the U.S. Department of Labor, was an attempt to codify safety regulations and to centralize the enforcement of statutes and standards in order to address the problem of accidents in industrial and other workplaces. OSHA was established through the National Institute for Occupational Safety and Health Act.

The industrial workplace had become a major locus of death and injury in the United States by the early twentieth century. The worker’s means of addressing prevention of accidents were limited, and the drive for profit provided little incentive for change. It was not until the
The accident is thus a “normal” aspect of complexly tight systems built by humans.

Unforeseen interactions between different system failures are unavoidable in nonlinear forms of production, because of exponential in their potential harm. Accidents thus are inherent in the systems, such that the outcomes are explosively explosive.

In the context of education, accountability refers to the concept that schools are responsible for ensuring that students meet agreed-upon standards of academic achievement. While governmental entities claim accountability is essential for the allocation of resources and the evaluation of policies and budgets, the term has taken on several distinct meanings. The principal dilemma was articulated by Susan Fuhrman and Richard Elmore (2004):

It is evident that what policy makers and the informed public think performance-based accountability is, differs considerably from what it actually is. In political discourse, it is common to hear both opponents and advocates speak as if test results were the metric of success in performance-based accountability … [but] the idea of equating student learning with test performance is suspect, both in terms of the technical characteristics of tests and the incentive effects of testing on instruction. (p. 275)

David Figlio and Cecilia Rouse (2006) suggest that accountability in the United States involves two distinct alternatives. The first is the use of test-based performance indicators, followed by sanctions for low-performing schools. The second alternative uses market forces to reward some schools and punish others as parents and students make personal resource- allocation decisions through the use of vouchers. Similar market-based accountability

systems occur through the exercise of enrollment choice in charter schools, magnet schools, or open-enrollment systems (Finn et al. 2000; Coulson et al. 2006). This article reviews accountability before recent changes in federal legislation and provides alternatives for consideration.

**COMPLIANCE-BASED ACCOUNTABILITY**

Until 2001 compliance-based accountability was the primary mechanism by which school systems and many other recipients of governmental funds were held accountable. If procedures were followed and rules were enforced, then the entity was sufficiently accountable. Despite the evidence that a lot of wasteful and counterproductive effort is spent on generating strategic plans and submitting proof of school improvement (Schmoker 2004; Reeves 2006), compliance-based accountability remains a dominant force throughout the United States and in many other national and provincial school systems.

**RESULTS-BASED ACCOUNTABILITY**

The prevailing example of results-based accountability is the No Child Left Behind (NCLB) Act of 2001, legislation that is scheduled for reauthorization in 2007. The essence of NCLB is a focus on results as defined by state test scores. While the law makes the National Assessment of Educational Progress (NAEP) a calibration device (Reeves 2001), it also allows each state to establish its own academic standards and its own assessment procedures. Thus, two states using the NAEP can show, respectively, 20 percent and 80 percent of students scoring at a proficient level—but show precisely the reverse when the “results” under consideration are scores generated by state-created tests. Moreover, results-based accountability emphasizes the effects of education without providing insight into the results. Wealthy schools have better results, but it does not necessarily follow that those results stem exclusively from better teaching, leadership, and policy, any more than poorer results in poor schools stem exclusively from inferior teaching, leadership, and policy (Rothstein 2004).

**HOLISTIC ACCOUNTABILITY**

To supplement exclusive reliance on test scores, expanded accountability systems have been employed in many school systems (see Reeves 2002, 2004a, 2004b). Holistic accountability is based on three tiers of indicators: system-wide indicators, including test scores; school-based indicators, including professional practices of teachers and educational leaders; and school narratives, providing qualitative context for quantitative data. One of the best examples of a governmental entity systematically examining both student achievement data and professional practices is provided by Alberta Learning, the system used in the Canadian province of Alberta (unlike the United States, Canada’s educational governance is decentralized). Alberta’s rigorous standards, consistent tests, holistic accountability system, public reporting, and long-term improvements in achievement suggest that accountability policies can be effective and constructive governance tools.

**VALUE-ADDED ACCOUNTABILITY**

A growing number of schools are using value-added accountability, in which progress is measured by comparing students’ present performance to their performance in previous years (Sanders 1998). As of November 2006, ten states have been authorized to experiment with this system. Value-added accountability has the advantage of showing more meaningful comparisons and focusing on growth in achievement, thus encouraging low-performing schools and challenging high-performing schools. Value-added models are complex and in some cases proprietary. Moreover, any test that can show progress will, of necessity, include items below grade level and above grade level. Such tests are not consistent with the prevailing NCLB requirement that state tests reflect grade-level academic standards. This inevitably leads to tradeoffs: A test that addresses multiple grade levels in order to allow students to “show progress” will require more items in order to maintain the reliability of the test—but more test items can subject students (and teachers) to “test fatigue,” which itself can impair the validity of the test. If, on the other hand, a fifth grade student takes a test with only fifth grade items on it, it would be possible for immense progress—say, from a second-grade to a fourth-grade reading level—to be substantially overlooked. Emerging models using item response theory are being experimentally implemented in some districts, notably by the Northwest Evaluation Association. Item response theory (IRT) is the study of test and item scores based on assumptions concerning the mathematical relationship between abilities (or other hypothesized traits) and item responses (Baker 2001). While the mathematics of IRT can be complex, the practical application in the realm of educational accountability and assessment is straightforward. Without IRT, every student would take the same test. Using IRT, each student would take a test uniquely suited to his or her abilities.

For example, if student A and B are taking a test of Grade 4 reading, student A might get the first question right, while student B gets the first question wrong. In a traditionally constructed test, both students would continue to take the same test, with student A doing well—in fact, failing to be challenged—while student B might
become increasingly frustrated, perhaps to the point of enduring test fatigue and giving up on the exam. Using IRT, however, student A would proceed to a more difficult question, while the next question given to student B would be easier.

**ACCOUNTABILITY GUIDELINES**

As educational accountability policies are revised in future years, leaders and policymakers can learn from the successes, errors, and unintended consequences of previous policies. In a wide variety of fields, opinions hold sway over evidence, and as Jeffrey Pfeffer and Robert Sutton (2006) warn, leaders are deluded by “dangerous half-truths” and “total nonsense.” Many faulty educational practices, often incorporated into detailed long-term strategic plans, continue, even though the evidence does not support them (Childress et. al 2006; Reeves 2006). While market-based accountability surely leads to definitive rewards and sanctions, the invisible hand of the market does not shed light on how accountability policies can be employed to attain their central aim—the improvement of school performance and student achievement. To advance this cause, three essential aspects of accountability need to be kept in mind:

1. **The purpose of accountability is to improve performance.** It is not merely a reporting vehicle used to rate, rank, and sort students, teachers, schools, and states. Therefore, of necessity, an effective accountability system must include not only results, but also inferences about how to improve results. An accountability system that includes only student test scores without a measurement of teaching and leadership practices is like a healthcare accountability system that counts death rates, but does not ask how patients died.

2. **Accountability requires coherent data.** To allow for hypothesis testing, data must be distributed and warehoused in a way that makes it accessible and usable. While national educational standards remain politically impossible, there should be national standards for accountability systems that would permit meaningful comparison of the data generated by them.

3. **The smaller the unit of analysis, the more meaningful inferences from the data will be.** The evidence on the impact of classroom teachers on student learning is overwhelming (Darling-Hammond and Sykes 1999). Goodlad (1990, 1994) also makes a persuasive case that the individual school leader can have a profound impact on student achievement. However, when considered on a larger scale, the relationship between policy and results is less clear. Attempts to track district-level “progress” are bedeviled by countless confounding variables. Even school-level accountability—the focus of present law—can lead to a label of success or failure for an entire school based on the performance of one group of students in one grade in one subject.

ACCOUNTING, GROWTH

SEE Solow Residual, The.

ACCUMULATION OF CAPITAL

Economists have used the term accumulation of capital to express several conceptual ideas in economics. Avoiding those having to do with obtaining more money, more bonds, or more stocks, two principal uses remain: an increase in the amount of physical means of production within an economy or its firms, or an increase in the power of the capitalist class. The former is the usage in neoclassical or mainstream economics while the latter is often considered within Marxist economics (although the exact meaning is still subject to various considerations). It is not unusual for either consideration to lead to discussion of economic crises, specifically to what might be their origins. The issue of crises may be, in turn, connected to disproportionalities among supplies and demands across industries within the economy.

EARLY DISCUSSIONS

In 1776 the Scottish economist Adam Smith made some attempt to define capital, but not its accumulation, while in 1821 the English economist David Ricardo introduced serious discussion of the effects upon workers of the introduction of new machinery, finding that it would not necessarily be beneficial. Ricardo was probably persuaded to undertake this investigation under the influence of the Swiss economist Jean-Charles-Léonard Simonde de Sismondi (1773–1842), whom Ricardo respected enough to visit from the United Kingdom. Sismondi was quite critical of the influence of capitalism upon the population and explicitly discussed the crisis aspects of capitalist development.

The German economist and political philosopher Karl Marx discussed accumulation of capital, yet there are ambiguities in his discussion. Marx was concerned, fundamentally, with the exploitation of the working class by the capitalist class and the capitalist class’s capability of earning surplus value off the workers. Surplus value is the difference between working time of workers and the time required to produce the goods workers are able to buy with their wages. His principal book Capital (1867) is precisely a focus on that exploitation, so his accumulation of capital ought to be understood as an increase in the numbers of workers being exploited, including the related requirement to have built the factories within which the workers would be working. Crises could result from disproportionalities in production but also from the inability to find outlets for all the products produced under capitalist relations when the standard of living for the mass of workers is continually depressed. The latter concern dates back to Sismondi and the English economist Thomas Malthus (1766–1834), yet has unique aspects of analysis in Marx. The emphasis, generally, on means of production (e.g., machinery) in referring to accumulation of capital did penetrate Marx to some extent and his writing on accumulation.

In the 1890s the Russian Communist leader Vladimir Lenin brought Marxist economic thought back toward Ricardo, and also included more emphasis on technological development and disproportionalities in production than would be consistent with Marx himself. Becoming leader of the Bolshevik Revolution in Russia in 1917, his influence on Marxist economic thought was greater than his depth of understanding of Marx’s political economy. Nevertheless, Lenin was not alone as Mikhail Tugan-Baranowsky (1865–1919) and the German economist and statesman Rudolf Hilferding (1877–1941) also emphasized disproportionalities in explaining crises.
talist system to find sufficient markets, since workers’ wages are naturally suppressed, capitalist luxury consumption has its limits (considering the massive quantities of products that can be produced), and producing more and more machines just for its own sake makes no sense. She criticized certain aspects of Marx’s work for failure to recognize the problem, even as she is firmly considered to be a Marxist economist.

Following upon the development of neoclassical economics beginning in the 1870s, John Bates Clark’s *The Distribution of Wealth* solidified a distinct interpretation of capital as a measure of machines, like acres of land. In other words, all those different types of machines in industrial society were to be reduced to a homogenous measure called real capital. However, unlike land, machinery is a produced element of the production process and is changing much of the time, not just in numbers, but in its very physical characteristics. This was a strange innovation on the part of Clark, but it allowed him to render a marginal productivity theory of income distribution to explain why workers, capitalists, and landowners get what they get out of the national output.

As the mathematization of mainstream economics proceeded apace, capital in the sense of Clark, including its accumulation, proceeded along with it, and the neoclassical production function became widespread, both at the microeconomic level of the firm as well as for national economies.

When Luxemburg’s book was translated into English in 1951 it had an introduction by Joan Robinson, and soon thereafter Robinson published her own book, *The Accumulation of Capital* (1956). Having come out of the Keynesian tradition of the 1930s that shared concerns of Malthus, Sismondi, and Marx regarding the possible deficiences of aggregate demand to sustain the mammoth crises of old, accumulation of capital proceeded along with it, and the neo-classical production function became widespread, both at the microeconomic level of the firm as well as for national economies.

When Luxemburg’s book was translated into English in 1951 it had an introduction by Joan Robinson, and soon thereafter Robinson published her own book, *The Accumulation of Capital* (1956). Having come out of the Keynesian tradition of the 1930s that shared concerns of Malthus, Sismondi, and Marx regarding the possible deficiences of aggregate demand to sustain the mammoth crises of old, accumulation of capital proceeded along with it, and the neo-classical production function became widespread, both at the microeconomic level of the firm as well as for national economies.

During the 1960s Clark’s conception of capital came under strong criticism when the so-called reswitching controversy arose. This controversy is too involved to summarize in this entry, but it starts with a proof that a simple economy, as wages moved in one direction, could switch from one technology to a second technology, and then, as wages continued to move in the same direction, switch back to the initial technology. The significance was to question how marginal productivity à la Clark could have any meaning.

Meanwhile, the Marxist tradition continued to refer to accumulation of capital as an expression of the inherent tendency of capitalism to extend its domination, but now connected to the possibility of a falling tendency of the average profit rate and thus to economic crises. By and large, accumulation of capital as a concept was anything but well defined and often functioned similarly to the term *capitalism*, with a more serious sound to it. A resolution that refers to increasing proletarianization of the world under the thrust of capital is not well accepted as of 2006.

**CONCLUSIONS**

Possible empirical work on accumulation of capital follows from the conceptualization. Should capital be measured as real capital then disparate physical items are typically aggregated by some type of weighting by relative prices exhibited in product markets. The trend of capital accumulation would therefore seem to be reflected in the increasing amounts of the individual items of equipment and structures. Yet, there are deep index number problems involved, including the initial base of the weighting, changing relative prices, and, most significantly, the introduction of totally new technologies and the disappearance of old (tractors substituting for iron plows pulled by horses, mules, or oxen; electrical lighting substituting for candles; cash registers for abacuses). In spite of difficulties, a whole segment of empirical economics has developed around such accounting, sometimes additionally integrated into profit-rate calculations.

Should capital be measured by capacity to exploit the labor hours of wage workers one would first have to measure the total employed wage workers and the length of their work hours. One would need to make a distinction between those who produce for capitalists commodities to be sold in the market and those who perform functions such as selling or administrative, as well as exclude those who do not work for capitalists (such productive/unproductive distinction appears, in differing forms, in portions of Smith’s and Marx’s works). At the level of an enterprise, data may be available, but for national economies they are much less so. No satisfactory work has been done on a global scale.

Achievement

---

**ACHIEVEMENT**

The modern scientific study of achievement began with Henry Murray’s seminal study of basic human needs, *Explorations in Personality* (1938). His definition of *achievement*, influential in all subsequent work on the subject, was “To accomplish something difficult. To master, manipulate or organize physical objects, human beings, or ideas. To do this as rapidly and as independently as possible. To overcome obstacles and attain a high standard. To excel one’s self. To rival and surpass others. To increase self-regard by the successful exercise of talent” (Murray 1938, p. 164). His definition of *achievement motivation* was “To make intense, prolonged and repeated efforts to accomplish something difficult. To work with singleness of purpose towards a high and distant goal. To have the determination to win. To try to do everything well. To be stimulated to excel by the presence of others, to enjoy competition. To exert will power; to overcome boredom and fatigue” (Murray 1938, p. 164).

**MEASURING ACHIEVEMENT**

Murray developed a list of twenty human needs. Of these, the Need for Achievement has been the most extensively studied (along with the Need for Affiliation and the Need for Power). Murray also created the most extensively used measure of achievement motivation, the Thematic Apperception Test (TAT). This test asks people to tell stories about each of several pictures of people in a variety of situations. Evaluators then code the stories for the presence of achievement themes. It is an indirect, or *implicit*, measure of interest in achievement, as opposed to an explicit measure in which people are asked to answer questions that probe for achievement motivation (as in the Achievement Motivation Inventory, an explicit adaptation of the TAT). The primary use for these measures is to discover how individuals differ in their degree of interest in achievement and, by implication, the strength of their achievement motivation.

David McClelland, using a refined version of the TAT, showed that child rearing practices have a relation to subsequent strength of achievement motivation, both at the level of the individual parent-child relationship (e.g., the extent of early independence training) and at the level of a society’s dominant culture of achievement. McClelland’s wide-ranging work at the level of culture-related differences between countries (in such things as the Protestant work ethic and the amount of achievement imagery in children’s texts or in the works of prominent writers) to indices of economic activity. This work demonstrated a clear and consistent relation between achievement imagery and economic development among and within nations and across a span of time from ancient Greek civilization to the mid-twentieth century, with increased levels of achievement themes preceding increases in economic productivity. Murray’s theory specified that the surrounding cultural context regarding achievement influenced the way that parents reared their children, which in turn created stable achievement motivation in those children as adults, eventually resulting in overall increases in the society’s economic output.

John Atkinson and his colleagues developed an influential *expectancy X value* theory of achievement motivation. The tendency to strive for success is, in this formulation, a multiplicative combination of the motivation to succeed, the value placed on success, and the likelihood of success. One of the primary findings using this analysis is that when given a choice among tasks varying in difficulty (probability of success), individuals will prefer tasks of intermediate difficulty, particularly if they are high in achievement motivation. The most likely reason
for this preference is that tasks of intermediate complexity are the best diagnostic tasks in that they give the most information about the meaning of success or failure for one's current level of proficiency. Another implication of this formulation is that when either the probability of success, or the value of success, is extremely low, little motivation to achieve will be generated.

UNDERSTANDING MOTIVATION
A more cognitive approach to achievement motivation emphasizes how individuals understand and explain successes and failures. Bernard Weiner proposed that explanations for performances vary in two dimensions. Explanations may be either internal (something about the performer) or external (something about the performance situation), and they also vary in whether the cause is stable (likely to be the same in the future) or unstable (likely to be different in the future). An explanation for a particular performance might be internal and stable (ability), internal and unstable (effort), external and stable (task difficulty), or external and unstable (luck). These explanations for performance affect both how individuals feel after success and failure, and how willing they are to persist in the face of an initial failure.

Initial differences in the kinds of explanations people are likely to use also have been shown to underlie the likelihood of persisting or quitting in the face of initial failure. A mastery orientation entails a focus on acquiring competence at the task, on the feeling of making progress and getting better. In the face of initial failure, a mastery orientation leads to attributions to effort, and supports task persistence. In contrast, with a performance orientation the goal is to show how good one is at the task. When a person takes this orientation, initial failure is likely to be interpreted as a sign of low ability and to lead to decreased task persistence.

STEREOTYPE THREAT
The expectations of others can strongly affect achievement. Stereotypes about how well or poorly a member of a particular group is likely to perform can strongly affect the actual achievement of members of the stereotyped group. Claude Steele and Joshua Aronson introduced the concept of stereotype threat. This research demonstrates that when negative performance stereotypes are present, actual performance suffers. For example, women who are quite good at math show poorer math performance in situations in which the stereotype that women are not as good at math as men is salient, showing that the stereotype itself leads to a self-fulfilling prophecy. Steele and Aronson's initial work showed that when stereotype about intelligence is made salient for African Americans in an SAT-like task, performance suffers. Underlying this process of stereotype threat is the fear that performing consistently with the stereotype will serve to confirm it in the minds of others. Worrying about this result unfortunately creates enough anxiety to interfere with performance and paradoxically results in the very behavior about which one is worried.

Achievement and achievement motivation are essential aspects of human nature, and are influenced by learning, by expectations of the value and probability of success, by one's own explanations for task performance, and by the beliefs and expectations of others.

ACHIEVEMENT GAP, RACIAL
The black-white achievement gap refers to disparities between African American (black) and European American (white) students on educational outcomes that include standardized test scores, grade-point averages, high school graduation rates, and college enrollment and completion rates. On each of these measures, white students typically outperform their black peers. While scholars have studied the gap in standardized test scores since the early 1900s, interest in this topic reemerged in the 1990s partly in response to a widening of the gap on the National Assessment of Education Progress in the United States after it had narrowed for nearly 20 years. This renewed interest also arose partly in response to the publication of the controversial book The Bell Curve, by
Richard J. Herrnstein and Charles Murray (1994), which suggested that the gap resulted from genetic differences between racial groups.

Genetic arguments have been rejected convincingly by research in which scholars identify multiple methodological flaws in such work and point out that the lack of systematic genetic variation across racial categories undermines such arguments. Other explanations for the racial achievement gap, however, have empirical support. For example, racial differences in social class as measured by parents’ education, income, and wealth explain a substantial portion of the gap in test scores and educational attainment. Additionally, research shows that black and white students receive different opportunities to learn, even when attending desegregated schools, and that these differences contribute to the gap. Black students are typically placed in lower-ability groups and educational tracks, are overrepresented in special education, are underrepresented in gifted and talented programs, are taught by less experienced and less well trained teachers, and face lower teacher expectations regarding their academic potential than white students.

Additional explanations focus on psychological and cultural mechanisms associated with the gap. For instance, the stereotype threat model devised by the psychologist Claude Steele (b. 1946) demonstrates that black college students underperform on academic tasks because they fear being viewed through the lens of negative racial stereotypes about black intelligence or are apprehensive about confirming such negative stereotypes through poor test performance. Stereotype threat may lead to a process called disidentification, in which black students’ personal identities become disconnected from education as a domain, leading to underachievement. More research, however, is needed to further test this hypothesis.

The oppositional culture argument provides a related explanation for the black-white achievement gap. Perhaps best articulated by the anthropologist John Ogbu (1939–2003) and his colleagues—for example, in the contribution to *Urban Review*, “Black Students’ School Success” (Fordham and Ogbu 1986)—this perspective suggests that black students respond to race-based educational and employment discrimination by opposing educational achievement. As a result, high-achieving black students may confront negative feedback from their peers for investing in school and receive criticism for “acting white.” While this has been an influential explanation for the gap in scholarly and popular discourse, recent research rejects its core hypotheses. Finally, while no scholarly consensus exists, some research suggests that schools, as institutions, respond favorably to and reward white students’ cultural styles (such as dress, linguistic practices, and learning styles) and devalue those of black students, perhaps contributing to the gap.

**WHY DID THE GAP CLOSE?**

It is unclear why the test-score gap narrowed between 1970 and 1988. However, work suggests that greater access to educational resources among black students, reductions in class size, and racial desegregation efforts may have contributed to this pattern. The gap persists in desegregated schools, however, probably because of racial inequalities in opportunities to learn in such contexts. Likewise, aggressive efforts to challenge systematic racial discrimination in educational and employment opportunities following the civil rights movement of the 1950s and 1960s may have led to greater optimism about the economic returns to education among African Americans and increased their already high levels of motivation for educational achievement.

**BIBLIOGRAPHY**

Tyson, Karolyn, William Darity, and Domini R. Castellino. 2005. It’s Not “a Black Thing”: Understanding the Burden of
ACTING WHITE

African American adolescents sometimes ridicule their peers for behaving in ways they identify as characteristic of whites. A variety of behaviors may trigger this response: manner of speech and dress, choice of television shows or sports, and, most troubling, demonstrating a commitment to academic success by participating in class, studying hard, and enrolling in advanced classes. This phenomenon was given prominence in an article published in 1986 by ethnographers Signithia Fordham and John Ogbu, reporting a study of a predominantly black high school in Washington, D.C. Since then, the burden of “acting white” has emerged as one of the standard explanations for the black-white gap in test scores and academic achievement; gifted black students are dragged down by peer pressure. But the evidence does not provide much support for the view that peer pressure against academic achievement is especially pervasive or important in influencing the academic striving of African Americans.

Ogbu speculated that black students tend to sneer at academic striving because they are influenced by an “oppositional culture” traceable to slavery, discrimination against blacks, and persistent inequality. Academic achievement is devalued because of its association with the dominant and oppressive white culture. A contrary view notes that while both black and white adolescents may sometimes exert (or experience) peer pressure against being “nerdy” and working hard in school, this anti-intellectual norm is not usually racialized.

Fordham and Ogbu reported on their observations from a single school. Several studies based on representative national surveys of high-school students have reached contrary findings. These have demonstrated that the differences between black and white students are negligible with respect to the value placed on education. Blacks express expectations at least as high as whites for graduating from high school and attending a four-year college. On average they attend class and expend as much effort outside of class as whites, and their parents are just as involved.

Whether there is a social penalty for academic success has also been investigated from national survey data. By a number of measures relating to social rejection, top students of both races do no worse (on average) than those in the middle of the grades distribution. Being in the honor society actually appears to protect against social ostracism, especially for black students in predominantly black schools. On the other hand, research by David Austen-Smith and Roland Fryer (2005) has found that the best black students have fewer close friends than those with average grades, especially in the case of males.

Since Fordham and Ogbu’s original contribution, there have been several more ethnographic studies of individual schools. These have tended to cast further doubt on the notion of the “burden of acting white.” A detailed survey of students in Shaker Heights, Ohio, by Harvard economist Ronald Ferguson (2001) has been especially influential. He found no evidence of an oppositional culture among the black students. Similar proportions of black and white students reported that there was a social penalty for academic striving in this successful and long-integrated school system. Another study of eight schools in North Carolina confirmed that there was some social penalty for high achievement for both races, but in only one of the schools were there reports of a strong racial element to this stigmatization (Tyson, Darity, and Castellino 2005). It did appear that qualified black students sometimes avoided taking advanced placement classes, but that was due more to a concern with being socially isolated (as possibly the only black student in class), rather than a concern with being criticized by their black peers.

The bottom line is that the adolescent norm against academic striving and success is evident among both white and black students. In some times and places, the successful black students are accused of “acting white,” but there is little evidence in support of a pervasive black cultural norm against academic striving and success. Finally, whatever the penalties, there are also social rewards for being successful, and in the rough-and-tumble of adolescent society, the top scholars are not doing any worse on average than their peers.

Activism

Activism refers to action by an individual or group with the intent to bring about social, political, economic, or even ideological change. This change could be directed at something as simple as a community organization or institution or as complex as the federal government or the public at large. In most cases, but not all, the action is directed toward the support or opposition of a controversial issue. Such issues range from basic human rights (see Blau and Moncada 2005) to the rights of gay men and lesbians (see Hunter et al. 1992) to antiwar or prowar sentiments over the Iraq War.

The First Amendment of the U.S. Constitution guarantees the right of the people to “petition the government for a redress of grievances.” While earlier drafts of the First Amendment simply addressed the needs of the people to assemble and petition, later drafts included the rights of free speech, freedom of the press, and religion. However, the right to these freedoms is a matter of debate. Laws such as the Patriot Act, passed shortly after the September 11, 2001, attacks on the World Trade Center in New York City and the Pentagon near Washington, D.C., expand the authority of U.S. law enforcement agencies under the rhetoric of terrorism and limit the constitutional rights of U.S. citizens. In addition, rights to assembly are often viewed by law enforcement agencies and government organizations as a political threat. As a result, there are countless cases in U.S. history where altercations between law enforcement and organizing groups, even peaceful assemblies, have resulted in violence. For instance, a rally in Los Angeles over immigration rights on May 6, 2007, was disrupted when police officers fired rubber bullets into the crowd and pummeled television crews and other journalists with batons (Kahn 2007).

Activism can take many forms, including such actions as civil disobedience, rioting, striking by unions, government or institutional lobbying, verbal or physical confrontation, various forms of terrorism, and the use of music and the media to draw attention to particular issues. The rise of the Internet has allowed new forms of activism to emerge and has also allowed many small, local issues to gain a wider audience and in some cases worldwide attention. Activism is a necessary vehicle for progressive and social change (see Bonilla-Silva 2006). Major movements such as the civil rights movement represent examples of what large-scale activism can accomplish given the right historical conditions and group collectivities.

In addition to individual or group-level activism, there are centers and organizations whose sole purpose is to promote social change through awareness and the bridging of theory and practice. Examples of such organizations include Loyola University–Chicago’s Center for Urban Research and Learning, a public sociology center that promotes research addressing community needs and that involves community organizers at all levels of its research process. Similarly, Project South, a leadership-development organization located in the southern United States, works with communities in bottom-up activism over issues pertaining to social, racial, and economic justice.

Activism, Judicial

Judicial activism is a philosophy that motivates judges to depart from strict adherence to judicial precedent, statutes, and strict interpretation of the United States Constitution. The juridical reasoning behind judicial activism is that the judiciary should have latitude in creat-
judging and interpreting law to protect the rights of political minorities from majoritarian excesses. Judicial activism has frequently been contrasted with judicial restraint. Judicial restraint means deference to other political branches, whether by upholding precedent or strictly interpreting statutory or constitutional provisions. The issue of judicial activism versus judicial restraint is volatile because of the consequences it can have on the law and society. Therefore, charges of judicial activism have been strategically used by both conservatives and liberals as concise campaign slogans to extol either the virtue or vice of the opposing candidate or political party. Many times, individuals affiliated with particular political parties or groups who view specific judicial decisions as conflicting with their philosophies characterize the judicial decision as an example of judicial activism. However, to discuss the issue in polarizing terms and apply political labels is overly simplistic. There are numerous Supreme Court decisions in the history of the United States, arguably results of judicial activism, that many would argue were constitutional milestones and others view as setbacks. Among these decisions are some of the most important landmark rulings in ensuring equity and fairness, as well as others that were patently flawed.

The landmark case Brown v. Board of Education (1954) ended the segregation in public schools that previously had been directed by the “separate but equal” doctrine. The decision overruled precedents and rejected state legislative statutes that allowed racial segregation in schools. In another example, in 1971 the Supreme Court in Reed v. Reed determined that the Equal Protection Clause of the Fourteenth Amendment guaranteed equality for women, and that a state law that discriminated based on gender was unconstitutional despite the fact that the Fourteenth Amendment does not state on its face that women and men should be treated the same. Most people today acknowledge that these Supreme Court rulings could be considered examples of judicial activism, but few would argue that they were not fair and just and should be overturned.

Judicial activism has also produced some less desirable results. In Dred Scott v. Sandford (1856), commonly known as the Dred Scott decision, the Supreme Court invalidated the Missouri Compromise and interpreted the Constitution as expressly allowing slavery, and held that people of African descent, whether or not they were slaves, could not be citizens of the United States. This was in direct contrast to the will of Congress, and set the scene for the Civil War.

An example of judicial restraint that resulted in a flawed decision is the Supreme Court ruling in Plessy v. Ferguson (1896), which stated that “separate but equal” public facilities met the requirements of the Fourteenth Amendment guarantees. Therefore, states could segregate facilities based on the color of a person’s skin. Examples of cases where judicial restraint produced positive results include the civil rights cases of 1964 in which the Supreme Court deferred to Congress and upheld the Civil Rights Act of 1964 (e.g., in Heart of Atlanta Motel, Inc. v. United States, 1964).

Neither judicial activism nor judicial restraint should be viewed as an absolute vice or virtue. Judicial activism and judicial restraint by the United States Supreme Court have both produced some of the wisest landmark decisions as well as some of the less desirable rulings. The U.S. experience with judicial review demonstrates that juridical philosophies defined as activism or restraint are not helpful in determining the quality of a judge or a judicial decision.

SEE Jefferson, Thomas.

ADAPTIVE EXPECTATIONS

The term adaptive expectations refers to the way economic agents adjust their expectations about future events based on past information and on some adjustment term. This implies some sort of correction mechanism: if someone’s expectations are off the mark now, they can be corrected the next time, and so on. Economists view decision rules that govern an agent’s behavior as being continuously under revision. As new decision rules are tried and tested, rules that yield accurate outcomes supersede those that fail to do so. In this sense, Robert Lucas (1986) refers to the trial-and-error process through which the models of behavior are determined as “adaptive.”

Suppose we want to forecast the inflation rate \((\Pi_t)\), which is itself measured by variations in the price index over time, \((P_t - P_{t-1})/P_{t-1}\). An example from an econom-
ics textbook (e.g., Arnold 2005, pp. 351–352) will help illustrate the principle of adaptive expectations. Let an individual forecast the future inflation rate for Year 5 based on the previous four yearly inflation rates. Observing the declining trend in the inflation rate over time, the forecaster assigns more weight to the more immediate past as follows:

- Year 1: 5% inflation rate with weight 10%
- Year 2: 4% inflation rate with weight 20%
- Year 3: 3% inflation rate with weight 30%
- Year 4: 2% inflation rate with weight 40%

The individual’s expected inflation rate, \( E(\Pi_5) \), will be:

\[
E(\Pi_5) = 0.05 (0.10) + 0.04 (0.20) + 0.03 (0.30) + 0.02 (0.40) = 0.030, \text{ or a 3 percent inflation rate forecast for Year 5.}
\]

More generally, inflationary expectations can be calculated by using a weighted average of past actual inflation (\( \Pi_t \)) and past expected inflation measured by \( E(\Pi_{t-1}) \):

\[
E(\Pi_t) = \lambda E(\Pi_{t-1}) + (1 - \lambda) E(\Pi_t)
\]

where: \( E(\cdot) \) is the expectations operator; and \( 0 < \lambda < 1 \) is the weight of past inflation on current inflation expectations. Algebraic manipulation of (1) yields:

\[
E(\Pi_t) = E(\Pi_{t-1}) + \lambda [E(\Pi_{t-1}) - E(\Pi_{t-1})]
\]

where the second term (in brackets) is composed by the weight and a forecast error of the previous rate of inflation. Inflationary expectations are thus the sum of the previous term inflation forecast and the forecast error. The error term is going to have a large effect on current inflationary expectations if the parameter \( \lambda \) is large. If \( \lambda \) is zero, the adjustment term vanishes and current expected inflation matches past expected inflation. If, on the other hand, \( \lambda \) is one, the current expected inflation rate equals the past inflation rate.

The adaptive expectations principle found plenty of applications in macroeconomics, such as in the analysis of hyperinflation by Philip Cagan (1956), in the consumption function by Milton Friedman (1957), and in Phillips curves for inflation and unemployment. The empirical success of the idea was ultimately challenged by the rational expectations hypothesis, developed by John Muth (1961) and extended by Thomas Sargent and Neil Wallace (1975) and Lucas (1976). More recent work, such as George Evans and Garey Ramey (2006), follows Muth (1960) and reconsiders the Lucas critique in the context of adaptive expectations.

**ADDICTION**

The term addiction, as applied to substance use, denotes an advanced level of dependence on a substance, marked by a compulsive need to obtain and consume it despite negative consequences. Dependency may consist of phys-
physical dependency, psychological dependency, or both. Physical dependency is characterized by withdrawal symptoms that occur if the substance is discontinued. This physical dependence thus produces a cycle in which the individual continues to use the substance to prevent the withdrawal symptoms. Psychological dependency, while no less powerful than physical dependency, refers to an individual’s perceived need for the substance. When the individual is unable to acquire the drug, negative psychological experiences may occur, prompting the individual to continue substance use. Individuals who experience addiction may find themselves unable to function effectively without the substance or substances to which they are addicted. What distinguishes addiction from less extreme forms of dependence is a loss of control and a markedly intense preoccupation with the substance.

The term addiction is not part of the clinical framework presented in the Diagnostic and Statistical Manual of Mental Disorders (DSM-IV-TR) of the American Psychiatric Association. Yet, the diagnostic classifications in the 2000 edition of the DSM-IV-TR acknowledge the symptoms of physical and psychological dependence, including withdrawal and tolerance. Withdrawal, the prominent feature of addiction, is characterized by physical symptoms and often by inability to function without the substance. Tolerance occurs when over time individuals experience a decreased substance effect or must increase their dosage of the substance to experience the same effect.

Individuals may develop addiction to a variety of substances, including alcohol and drugs. Drugs of addiction include both illicit drugs like heroin and prescription or over-the-counter drugs like prescription oxycodone. Whether individuals can become addicted to behaviors—such as gambling, eating, and sexual promiscuity—is, however, controversial. Scholars who favor an expanded definition of addiction argue that certain behaviors may serve an emotion-regulating function and can thus lead to addiction.

The use of potentially addictive substances is quite prevalent. According to the 2004 National Survey on Drug Use and Health (NSDUH), 7.9 percent of the population aged twelve or older used illicit drugs in 2004 (Substance Abuse and Mental Health Services Administration [SAMHSA] 2005). However, substance use and addiction are not equally prevalent in all social categories. According to the 2004 NSDUH, rates of illicit drug use among those twelve and older increase until ages eighteen to twenty, after which rates gradually decrease (SAMHSA 2005). Rates of current illicit drug use also vary by race/ethnicity, with rates highest among individuals reporting two or more racial/ethnic groups and those of American Indian or Alaskan Native descent (SAMHSA 2005). Rates are similar for whites, Hispanics, and blacks, but markedly lower among Asians (SAMHSA 2005). With regard to socioeconomic status, rates are higher for the unemployed than the employed (SAMHSA 2005).

In addition to variations by social category, distinct patterns are observed for different classes of drugs. Tobacco and alcohol use are even more prevalent than illicit drug use (SAMHSA 2005).

CAUSES OF ADDICTION

Differences in patterns of use may be due to both social and biological factors. Furthermore, factors involved in initial and in continued substance use may differ. For example, individuals may begin use as a means of social enhancement or in response to pressure from peers and may continue use to avoid negative emotions or withdrawal.

Animal models have improved understanding of addiction and, in tandem with the findings of twin studies, strongly suggest a genetic component (see Crabbe 2002 for review). Scientists have identified neurotransmitter systems that are involved in the development of addiction. In recent years, this genetic component has received increasing attention as research on addiction has shifted from the domain of sociologists and psychologists to that of geneticists and neurobiologists. This focus on the role of brain chemistry (e.g., Koob, Sanna, and Bloom 1998) and genetics (e.g., Nestler 2000) has many potential implications for the study and treatment of addiction: It may lead to revolutionary new treatments and reduce addiction’s stigma. Especially useful are gene-environment interaction models in which social environments/circumstances and genetics interact to determine whether an individual develops addiction.

CONSEQUENCES AND TREATMENT OF ADDICTION

Addiction is costly to both society and the individual. At the societal level, the prevention, control, and treatment of addiction require substantial resources. The types of societal investments made depend in part on whether addiction is viewed as primarily a medical or a criminal issue. Policies based on medical models favor rehabilitation and other treatments and generally attempt to minimize the stigma of addiction. Policies based on criminal models focus on punishing addicts and deterring addiction in the same way that other crime is deterred. In practice, both policies, or elements of both policies, are observed.

Addiction usually entails a variety of social costs as well. Individuals with addictions are highly motivated to attain the substance of their addictions and may engage in
self-destructive behaviors or criminal acts in this pursuit. Drugs per se do not necessarily make individuals more violent, but the need to attain the drug, often to ward off withdrawal, may disinhibit individuals and lead to unhealthy and/or criminal activity. At the familial level, parents who have an addiction may be unable to responsibly care for their children. Moreover, children of substance users are themselves at increased risk of substance use (see, e.g., White, Johnson, and Buyske 2000). At the individual level, addiction is associated with a multitude of negative health effects. This may be due to the substance itself or to the way that the substance is consumed. For example, drugs that are smoked may contribute to lung cancer, whereas drugs that are taken intravenously pose risks associated with injection (i.e., use of unsterile needles may be associated with the transmission of infectious diseases like HIV). Negative health effects also include withdrawal, which can be fatal with some drugs and with alcohol if not medically supervised.

**TREATMENT OF ADDICTION**

Many agencies exist to assist individuals in overcoming addiction, including outpatient facilities, residential communities, and hospital-based programs. In addition, self-help groups like Alcoholics Anonymous (AA) are quite common. The twelve-step model of AA has been embraced by the treatment community and often provides the structural framework for both inpatient and outpatient treatment. A variety of pharmacotherapies are available for treating addictions, including agonist medications, antagonists, agonist-antagonist medications, and anticraving medications (see O’Brien 1997 for discussion). Supervised medical detoxification may be required for individuals addicted to certain drugs and for alcohol-dependent individuals with medical problems. Treatment for addiction can be quite costly.

Approaches to the treatment of addiction are predominantly based on a biopsychosocial model, which holds that the biological, psychological, and social bases of addiction all need to be addressed. Within that approach, differences in understandings of the causes of addiction may prompt some treatment providers to favor certain approaches over others. For example, some treatment providers favor a medical model in which addiction is viewed as a disease and treated within a medical framework, whereas others may lean toward more behavioral models that conceptualize substance abuse as resulting from deficient coping skills. Some providers more than others pay special attention to social and cultural explanations for addiction and advocate culturally sensitive programs that focus on overcoming social disadvantage. Individualized treatment programs and programs that respond to differences in gender and sexual orientation have great potential for success.

Addiction is a phenomenon with social, medical, and legal dimensions. A multifaceted public health problem, its treatment and prevention require contributions from multiple disciplines. Medical scholars, legal scholars, sociologists, psychologists, and policymakers are all needed if progress is to be made.

**ADMINISTRATIVE LAW**

Administrative law is a branch of public law that includes the laws and legal principles pertaining to the administration and regulation of state agencies, ministries, or departments and the relationship of the state with private individuals. It is a product of the need for a state to perform a multitude of functions for its citizens and deals with the decision making of a state agency in relation to its regulatory framework. Such regulatory frameworks perform a variety of state functions including natural resource protection, transportation regulation, and food
and health safety regulations. Because all administrative law systems are not the same it is imperative for an individual to have knowledge of the political, historical, social, and economic context of the system of a particular state to fully understand its administrative law. In most systems a state’s constitution or fundamental law is inextricably linked to its administrative law system and must be considered in light of the system or tradition under consideration.

All but the most oppressive administrative law systems share at least one or more of the following interests: (1) providing justice for injuries inflicted by state personnel and agencies on private citizens; (2) maintaining the legality and propriety of subordinate state agencies and actors; and (3) remediying injuries to bureaucrats by the state. Common law administrative law scholars in the United Kingdom and the United States look to the Conseil d’Etat in France because, at one time, French administrative law dominated continental systems. Not all administrative law systems conform, however, to this pattern. At least four other divergent themes have all been noted by H. B. Jacobini in An Introduction to Comparative Administrative Law (1991): “(1) the Sinitic Censorate and its derivatives, (2) the Procuracy and other administrative law procedures as found in the communist world, (3) the concept of the ombudsman, and (4) machinery for registering complaints” (p. 12).

The fundamental elements of administrative law in the United States that are similar to many European and other nations include: (1) statutory delegation of powers from an elected legislative body to the executive; (2) an administrative agency that derives its authority from the legislative body, and that implements the relevant law through rulemaking, adjudication, or other forms of administrative process; (3) judicial review by an independent judiciary of the administrative body’s actions for compliance with the statutory delegation of powers by the legislative body and other applicable laws; and (4) transparency of the decisional process.

For example, in the United States, administrative agencies are said to have no inherent powers because they must act pursuant to the legal authority delegated to them by the legislative body. The legislative body empowers administrative agencies to act as agents for the executive branch of government through statutory law. The statute that delegates power to an administrative agency sets forth the scope of the agency’s authority. Thus, the nature of administrative law is subconstitutional in the United States because the powers of administrative agencies are delegated through statutory law, not through constitutional law. Yet the actions of the administrative agency must ultimately comply with the U.S. Constitution, its fundamental law. In contrast the German Constitution, the Grundgesetz, contains provisions specifically relevant to the development of its administrative law system.

Administrative agencies in the United States typically utilize adjudication, rulemaking, and inspection to execute their statutory authority. Adjudication can be either informal or formal and must comport to the U.S. Constitution’s due process clause. Rulemaking can also be informal or formal. In addition, the power of inspection is sometimes used as a substitute for adjudication procedures or to determine whether not the existence of certain conditions warrant further administrative action. One example of an administrative agency is the Environmental Protection Agency (EPA), whose mission is to protect human health and the environment.

In many countries the courts play a large part in the development of administrative law. In the United States the power of judicial review allows courts to determine whether or not the actions of administrative agencies exceed the scope of their delegated authority or violate the Constitution. Similar processes of review are found in other countries and, although the legal standards vary, their roles are quite similar. For example, in France the Conseil d’Etat has developed general principles for administrative law. In the United Kingdom, the ordinary courts are competent in administrative law and, generally, this area is subject to common law. There, the Queen’s Bench of the High Court is more administrative than the ordinary court when it deals with applications of judicial review.

ADOLESCENT PSYCHOLOGY

Adolescence spans the second decade of life, a phase social scientists describe as beginning in biology and ending in society. Adolescence may be defined as the life-span period in which most of a person’s biological, cognitive, psychological, and social characteristics are changing in an interrelated manner from what is considered childlike to what is considered adultlike. When most of a person’s characteristics are in this state of change the person is an adolescent.

CHANGING MODELS OF ADOLESCENCE

Since the founding of the scientific study of adolescent development at the beginning of the twentieth century the predominant conceptual frame for the study of this age period has been one of storm and stress, or of an ontogenetic time of normative developmental disturbance (Freud 1969). Typically, these deficit models of the characteristics of adolescence were predicated on biologically reductionist models of genetic or maturational determination (Erikson 1959, 1968) and resulted in descriptions of youth as broken or in danger of becoming broken (Benson, Scales, Hamilton, and Sesma 2006), as both dangerous and endangered (Anthony 1970), or as problems to be managed (Roth, Brooks-Gunn, Murray, and Foster 1998). In fact, if positive development was discussed in the adolescent development literature—at least prior to the 1990s—it was implicitly or explicitly regarded as the absence of negative or undesirable behaviors. A youth who was seen as manifesting behavior indicative of positive development was depicted as someone who was not taking drugs or using alcohol, not engaging in unsafe sex, and not participating in crime or violence.

Beginning in the early 1990s, and burgeoning in the first half decade of the twenty-first century, a new vision and vocabulary for discussing young people emerged. Propelled by the increasingly more collaborative contributions of scholars (Benson et al. 2006; Damon 2004; Roth & Brooks-Gunn 2003), practitioners (Floyd & McKenna 2003; Little 1993; Pittman, Irby, and Ferber 2001), and policy makers (Cummings 2003; Gore 2003), youth are viewed as resources to be developed. The new vocabulary emphasizes the strengths present within all young people and involves concepts such as developmental assets, moral development, civic engagement, well-being, and thriving. These concepts are predicated on the ideas that every young person has the potential for positive youth development (PYD).

This vision for and vocabulary about youth has evolved in the context of the growth of developmental sys- tems, theoretical models that stress that human development derives from dynamic and systemic (and therefore bidirectional and mutually influential) relations among the multiple levels of organization that comprise the human development system. Developmental systems theory eschews the reduction of an individual to fixed genetic influences and, in fact, contends that such a hereditarian conception of behavior is counterfactual. Instead, developmental systems theory stresses the inherent plasticity of human development, that is, the potential for systematic change throughout development. This potential exists as a consequence of mutually influential relationships between the developing person and his or her biological, psychological, ecological (family, community, culture), and historical niche.

These mutually influential relationships involve the influence of a young person on his or her context (e.g., his or her influences on parents, peers, teachers, and community) and the influence of the components of his or her world on him or her. Termed developmental regulations, these bidirectional influences constitute the key focus of empirical study in contemporary research on adolescent development. When the exchanges between individual and context are mutually beneficial, developmental regulations are termed adaptive, and healthy, positive individual development should occur.

Plasticity, then, is instantiated from the regulation of the bidirectional exchanges between the individual and his or her multilevel context. Thus, the concepts of relative plasticity and developmental regulation combine to suggest that there is always at least some potential for systematic change in behavior and, as such, that there may be means found to promote positive development in adolescence.

Thus, plasticity legitimizes an optimistic view of the potential for promoting positive changes in youth. The presence of plasticity in development is a key strength of human development; when combined with the concept of adaptive developmental regulation, and when there is an alignment between the assets of an individual and the assets for positive development that exist in the ecology of youth, one may hypothesize that PYD will be promoted.

The key features of adolescent development underscore the importance of focusing on developmental regulations, in person-context relations, to understand the basic developmental process during this period. This focus allows as well an understanding of how plasticity may eventuate in PYD.

FEATURES OF ADOLESCENT DEVELOPMENT

Adolescent development involves adjustments to changes in the self (e.g., pertinent to puberty, cognitive and emo-
Adolescence is a period of extremely rapid transitions in physical characteristics. Indeed, except for infancy, no other period of the life cycle involves such rapid changes. While hormonal changes are part of the development of early adolescence, they are not primarily responsible for the psychological or social developments during this period. Instead, the quality and timing of hormonal or other biological changes influence, and are influenced by, psychological, social, cultural, and historical factors.

Good examples of the integrated, multilevel changes in adolescence arise in the area of cognitive development during this period. Global and pervasive effects of puberty on cognitive development do not seem to exist. When biological effects are found they interact with contextual and experiential factors (e.g., the transition to junior high school) to influence academic achievement. Perspectives on adolescence that claim that behavioral disruptions or disturbances are a universal part of this period of life might lead to the assumption that there are general cognitive disruptions inherent in adolescence. However, evidence does not support this assumption. Rather, cognitive abilities are enhanced in early adolescence as individuals become faster and more efficient at processing information—at least in settings in which they feel comfortable in performing cognitive tasks.

Thus, relations among biology, problem behaviors associated with personality, and the social context of youth illustrate the multiple levels of human life that are integrated throughout adolescent development. For example, in 1993 researcher Avshalom Caspi and colleagues linked the biological changes of early pubertal maturation to delinquency in adolescent girls, but only among girls who attend mixed-sex schools; similarly, Hakan Stattin and David Magnusson linked pubertal maturation and delinquency with girls who socialize with older friends instead of same-age friends. Early maturation among girls in single-sex schools or in sex-age peer groups was not linked with higher delinquency.

ADOLESCENCE AS AN ONTOGENETIC LABORATORY

Given the structure and substance of the range of interrelated developments during adolescence, from the late 1970s to the mid-2000s researchers have come to regard adolescence as an ideal natural ontogenetic laboratory for studying key theoretical and methodological issues in developmental science. There are several reasons for the special salience of the study of adolescent development to understanding the broader course of life-span development.

First, although the prenatal and infant period exceeds adolescence as an ontogenetic stage of rapid physical and physiological growth, the years from approximately ten to twenty not only include the considerable physical and physiological changes associated with puberty but also mark a time when the interdependency of biology and context in human development is readily apparent. Second, as compared to infancy, the cognizing, goal-setting, and relatively autonomous adolescent can, through reciprocal relations with his or her ecology, serve as an active influence on his or her own development, and the study of adolescence can inform these sorts of processes more generally. Third, the multiple individual and contextual transitions into, throughout, and out of this period, involving the major institutions of society (family, peers, schools, and the workplace), engage scholars interested in broader as well as individual levels of organization and provide a rich opportunity for understanding the nature of multilevel systemic change.

Finally, there was also a practical reason for the growing importance of adolescence in the broader field of developmental science: As noted by Laurence Steinberg and Amanda Sheffield Morris in 2001, the longitudinal samples of many developmental scientists who had been...
studying infancy or childhood had aged into adolescence. Applied developmental scientists were also drawn to the study of adolescents, not just because of the historically unprecedented sets of challenges to the healthy development of adolescents that arose during the latter decades of the twentieth century, but because interest in age groups other than adolescents nevertheless frequently involved this age group. For example, interest in infants often entailed the study of teenage mothers and interest in middle and old age frequently entailed the study of the middle generation squeeze, wherein the adult children of aged parents cared for their own parents while simultaneously raising their own adolescent children.

CONCLUSIONS
The theoretically interesting and socially important changes of adolescence constitute one reason why this age period has attracted increasing scientific attention. To advance basic knowledge and the quality of the applications aimed at enhancing youth development, scholarship should be directed increasingly to elucidating the developmental course of diverse adolescents.

In turn, policies and programs related to interventions must factor in adolescents’ specific developmental and environmental circumstances. Because adolescents are so different from one another, one cannot expect any single policy or intervention to reach all of a given target population or to influence everyone in the same way. Therefore, the stereotype that there is a single pathway through the adolescent years—for instance, one characterized by inevitable “storm and stress”—cannot be expected to stand up in the face of contemporary knowledge about diversity in adolescence. In future research and applications pertinent to adolescence, scholars and practitioners must extend their conception of this period to focus on changes in the individual characteristics of a youth and his or her complex and distinct ecology.

The future of civil society in the world rests on the young. Adolescents represent at any point in history the generational cohort that must next be prepared to assume the quality of leadership of self, family, community, and society that will maintain and improve human life. Scientists have a vital role to play in enhancing, through the generation of basic and applied knowledge, the probability that adolescents will become fully engaged citizens who are capable of, and committed to, making these contributions. As evidenced by the chapters in Richard M. Lerner and Laurence Steinberg’s Handbook of Adolescent Psychology (2004), high-quality scientific work on adolescence is being generated at levels of study ranging from the biological through the historical and sociocultural. As the work in this volume demonstrates, the study of adolescent development at its best both informs and is informed by the concerns of communities, of practitioners, and of policy makers.

ADVERSE SELECTION

The concept of adverse selection is used to identify a market process in which low-quality products or customers are more likely to be selected as a result of the possession of asymmetric information by the two sides of the market transaction. In this situation the better-informed side may
take trading decisions that adversely affect the other side, with unwelcome consequences for the market as a whole. Economists usually refer to this situation as a case of market failure: a case in which market dynamics do not lead to an efficient allocation of goods and services.

The notion of adverse selection is applied widely in contemporary economic literature because asymmetric information is often a common feature of market interactions. This typically occurs when the private information available to the sellers is not disclosed to the buyers or vice versa. The most classic example of adverse selection concerns the market for secondhand cars, which usually is referred to as the “market for lemons” since the pioneering work in 1970 of the Nobel laureate economist G. A. Akerlof.

In that market potential buyers cannot distinguish good cars (“peaches”) from bad cars (“lemons”) easily. However, the sellers are perfectly aware of the characteristics of their cars. Potential buyers are likely to offer the average market price for a particular car model. A peach owner will refuse such an offer, but a lemon owner will agree to sell his or her car for an amount that is likely to be higher than its real value. As a consequence, only sellers with bad cars will offer them for sale, and the potential buyers’ willingness to pay for secondhand cars will decrease. The resulting market equilibrium will be inefficient because there will be a number of transactions that are lower than the optimal level.

The role of adverse selection in explaining market inefficiencies has been understood since the beginnings of the economic literature. In his 1776 inquiry on the wealth of nations Adam Smith implicitly applied the concept of adverse selection to the analysis of the credit market. He intuited that a legal rate for loans much above the lowest market rate will probably attract only risky borrowers who are willing to pay a high interest rate. Safe borrowers, who are willing to pay only part of what they are likely to gain through the use of money, will not venture into the competition, and most of the capital probably will be lost.

Inefficiencies in the credit market caused by adverse selection have been used more recently to explain the causes of the Third World debt crisis of the early 1980s. Much of that debt was amassed after the 1973 oil crisis, when European and North American banks lent large amounts of money from the oil revenues deposited in their accounts. The low interest rate that was demanded attracted several Third World countries whose financial capability was not observable by those banks. For some of those countries strong financial constraints resulted in the inability to repay the debt when economic conditions worsened and interest rates increased.

ADVERTISING
Advertising is a form of mass media designed to promote a specific product, service, or idea on behalf of a business or organization. Advertisers ordinarily use media such as television, radio, print (magazines, newspapers, and billboards), sponsorship of cultural and sporting events, and the Internet.

From the Industrial Revolution to the mid-twentieth century, advertising in the United States and Europe was generally straightforward and usually included an image and description of the product’s function, price, and location to be purchased. According to William M. O’Barr in his 2006 article “Representations of Masculinity and Femininity in Advertising,” ads were primarily directed toward women because they were responsible for the majority of consumer purchases, the exception being “big ticket” products like cars and major appliances. Since World War II, however, industries have increasingly courted the adult male consumer, and with the advent of youth culture, children, teenagers, and young adults have been targeted as well.

A common strategy for advertisers is to make the consumer feel as though the given product will remedy a specific problem or insecurity. Designers prey on a modern culture obsessed with status, self-enhancement, youth, body image, and gender identity, the latter being a favored theme now aimed at both men and women. Critics such as John Kenneth Galbraith (1969) and Christopher Lasch (1978) charged that advertising functions to create desires that previously did not exist and that advertising serves to promote consumption as a way of life.

A dialectical relationship exists between consumers and advertisers where ads face heavy skepticism and scrutiny, while at the same time receive access and appreciation in the form of high revenue, lavish award ceremonies, and TV programs devoted to airing successful commercials. In the United States, argued Michael Schudson in his 1984 book Advertising, the Uneasy

INTERNATIONAL ENCYCLOPEDIA OF THE SOCIAL SCIENCES, 2ND EDITION
Persuasion: Its Dubious Impact on American Society, the culture is amenable to advertising that is “more pervasive and more intrusive than in any other industrialized country” (p. 128). Millions watch the United States’s Superbowl programming not for the content of the football game, but rather just to see the premier of new, multimillion-dollar ads.

A crucial difference between previous eras and today is advertising’s saturation. In U.S. and European cities a conservative estimate of people’s daily exposure to ads is 250 messages a day, while others suggest that that number is closer to 5,000 messages a day. This ubiquity creates a more skeptical and desensitized audience. As a result marketers go to greater lengths to make their products stand out.

Advertisers now use more diverse and insidious mediums such as stickers on food, social networking websites like YouTube, motion sickness bags, and space within public schools. Guerrilla marketing practices like “product placement”—where the intended audience is unaware that they have been exposed to an advertisement, while the desired impression of the given product remains—are now everyday tactics. In 2007 blinking electronic signs promoting a television show were surreptitiously planted on highways and bridges in Boston and mistaken for terrorist bombs.

Given the use of more sophisticated technology and the expansion of the Internet, marketers can better assess the effectiveness of their pitches and the return on investment. Sophisticated techniques like data mining help identify (and subsequently create) niche consumption desires. Additionally hyperspecialized media outlets enable advertisers to target more precise demographics. For example advertisers now design ads for gay men and air them on gay-oriented cable television channels like “Here TV” and “Logo.” Targeted marketing and reliable measurements of effectiveness are the holy grail of companies seeking to reduce costs.

In an era of global capitalism, advertising agencies work for clients all over the world and target niche demographics in nearly all continents. Successful advertising for multinational corporations hinges on the familiarity with local habits, symbols, and cultural differences. According to Marieke K. de Mooij in the 2005 publication Global Marketing and Advertising: Understanding Cultural Paradoxes, for a global brand like McDonald’s—a company that sells its food via more than 30 thousand distribution points, in 119 countries, serving 47 million customers a day—particular attention must be paid to local culture for the pitch to be successful. For example, advertising for McDonald’s in France tied into “Asterix and Obelisk,” the most famous historical cartoon of the nation (Mooij 2005).

As more advertising proliferates in the globalized context, we are likely to see new, unforeseen forms of consumer reluctance and resistance. Companies will surely continue to manage this dialectic for their own financial advantage.

AESTHETICS
The philosophy professor and writer Jerrold Levinson defines aesthetics as “the branch of philosophy devoted to conceptual and theoretical inquiry into art and aesthetic experience” (Levinson 2003, p. 3). What makes an experience an aesthetic one is a contentious matter, however, and is indeed one of the main subjects of the theoretical inquiry. Nonetheless, there is general agreement that people experience something aesthetically when, for example, they find it beautiful, elegant, or vulgar. Levinson’s definition, which is a fairly orthodox one, indicates that aesthetics developed out of different, though overlapping, concerns: for art, and for an allegedly distinctive type of human experience. The two are different because not only artworks, but also natural scenes and objects encountered in “everyday life” (coffee-machines, say), may be appreciated for their aesthetic qualities, such as garishness or symmetry. In addition, not all philosophical questions about artworks are about their aesthetic properties (e.g., questions about the role of poets’ intentions in determining the meaning of poems). The two concerns overlap, however, because the identification of an artwork’s aesthetic qualities is often an important ingredient in its appreciation.
Levinson’s definition blends two early and different ways of using the term aesthetics. Derived from a Greek word for “sensation,” it was first introduced by the German philosopher Alexander Baumgarten in 1735 as a name for “the science of how something … is sensitively cognized” (Baumgarten 1954, §16). The scope of the term was later restricted by Immanuel Kant, in his *Critique of Judgement* (1790), to sensation-based judgments of taste or beauty. For Kant, aesthetics had nothing peculiar to do with art. G. W. F. Hegel, however, doubted the possibility of a general “science” of beauty, and in his *Lectures on Fine Art* in the 1820s he equated the term with “the philosophy of fine art.”

Of course, although aesthetics was an eighteenth-century coinage, the discipline it refers to has an ancient pedigree. Plato and Aristotle, for example, addressed such paradigmatically aesthetic topics as beauty and the role of emotion in art.

Reflecting the divergent approaches of Kant and Hegel, later aestheticians have often been divided between those focused primarily on the philosophy of art and those concerned with understanding the character of aesthetic experience. Attention of the latter sort has tended to concentrate on an examination of Kant’s characterization of aesthetic experience as “disinterested,” as disengaged from cognitive and practical interests, and therefore sensitive solely to the appearances and forms of things.

Within philosophy, the status of aesthetics is disputed. For some it is a relatively discrete subdiscipline, while for others it is necessarily parasitic on the insights of other areas of philosophy, including metaphysics. Some thinkers, such as Friedrich Nietzsche, have held that its place is central, since aesthetic concepts such as style and elegance are involved in ethical reflection on the good life and even in philosophical reflection on scientific method.

The relation of aesthetics to the social sciences is also disputed, but many philosophical questions about art and aesthetic experience are certainly closely related to social-scientific issues, and aestheticians often invoke the findings of social science. One such question is “What is art?” John Dewey and Thorstein Veblen, for example, argued against “timeless” conceptions of art. They maintained that the modern concept of art is a nineteenth-century product that reflects the predilections of a dominant and leisureed social class. A related theme was developed in Pierre Bourdieu’s “social critique” of such distinctions as that between aesthetic and less “pure” pleasures.

Several issues concerning aesthetic experience, especially that of beauty, also engage with cultural anthropological ones. Thus, there has been considerable debate about whether there are broadly universal standards of, say, women’s beauty, explicable perhaps in terms of evolutionary factors, or whether such standards are relatively “local” ones, explained instead as functions of cultural pressures exerted by advertisers and the fashion industry. While aestheticians both contribute to and draw upon such empirical debates, most of them also maintain that these debates involve conceptual and evaluative issues that it is not for empirical enquiry to settle, but that instead call for philosophical analysis.

**AFFECT-INFUSION MODEL**

**SEE** Mood Congruent Recall.

**AFFIRMATIVE ACTION**

The term affirmative action refers to policy measures designed to reduce the marginalization of groups that have historically suffered from discrimination, exclusion, or worse, and that are underrepresented in a society’s desirable positions. The measures may take the form of public laws, administrative regulations, and court orders, or of practices by private businesses and nonprofit institutions. The underrepresented groups are typically “identity groups” defined in terms of characteristics that are physical or cultural, such as race, caste, tribe, ethnicity, and gender.

Affirmative action policies are designed to benefit members of underrepresented identity groups by providing them with more favorable access to certain benefits—usually positions such as jobs, promotions, or admissions...
to educational institutions, but sometimes resources such as business loans and contracts, financial aid, or land rights. Membership in an identity group recognized as underrepresented is treated as a positive factor, increasing one's chances of access to such benefits. This may be accomplished by means of a quota system, in which certain benefits are reserved for members of the relevant groups, or by means of a preferential boost system, in which extra weight is accorded to group members in an explicit or implicit measure of qualifications for access to benefits.

Affirmative action in the United States owes its origin to the civil rights movement of the 1950s and 1960s, which demanded an end to the long history of injustices perpetrated against African Americans and called for their full participation as citizens in U.S. society. This movement prodded the U.S. federal government into action to curb the segregation of African Americans into inferior facilities and to provide them with access to rights and opportunities long denied. The term affirmative action was first mentioned by President John F. Kennedy in his Executive Order #10925 of March 1961, which established the President's Committee on Equal Employment Opportunity and described positive steps to be taken by federal agencies to root out discrimination against any identity group.

Affirmative action in this sense gained a firm legal foundation in the Civil Rights Act of 1964, championed by President Lyndon B. Johnson and enacted in the wake of the assassination of President Kennedy. Reinforcing the antidiscrimination provisions of the act, President Johnson went on to issue a series of executive orders designed to promote equal opportunity in employment, education, and government contracting. It was initially expected that the assertion of formal legal equality of all citizens, the removal of overtly discriminatory barriers, and a much wider diffusion of relevant information to members of underrepresented groups would lead to significant increases in opportunities for members of such groups—in particular, African Americans. It soon became apparent, however, that affirmative action of this kind would not have a significant impact on the numbers of African Americans in desirable jobs or schools. By the late 1960s, therefore, many government agencies and private organizations began to give some preference to African Americans in selection processes. In this context the term affirmative action came to denote positive action in favor of members of underrepresented groups, not simply an effort to abolish all forms of discrimination.

Following the example set by African Americans, other identity groups underrepresented in desirable positions in the United States—such as women, Hispanic Americans, and Native Americans—began to mobilize in the late 1960s and early 1970s for policies to end discrimination and to facilitate improvement of their standing in U.S. society. Soon thereafter, affirmative action programs oriented to African Americans came to include also Hispanic Americans and Native Americans as beneficiaries; and a variety of public and private affirmative action programs were established to increase the representation of women in fields that had long been dominated by men.

Affirmative action has been practiced in many countries of the world. Beyond the United States, significant affirmative action policies are in place in India, South Africa, Malaysia, and Sri Lanka; and some form of affirmative action has been implemented in another dozen countries. India was the first site of such policies—labeled “reservations” since they involved quotas of reserved seats. In the early twentieth century popular movements against Brahmins—the highest Hindu caste, whose members dominated the most elite positions open to Indians under British colonial rule—led in parts of India to the establishment of reserved seats for non-Brahmins in some public services and educational institutions. In the 1930s reservation policies were implemented throughout British India in the form of legislative assembly seats reserved for four of India’s minority communities—Muslims, Christians, Sikhs, and Anglo-Indians—and later also the two most depressed communities—untouchables and tribals, officially labeled “Scheduled Castes” and “Scheduled Tribes.” The constitution of independent India, completed in 1950, is unusual in making explicit provision for affirmative action in the form of reservations for Schedules Castes and Scheduled Tribes in national and provincial assemblies, as well as in public sector jobs and public institutions of higher education. The Indian constitution also permits reservations for members of “Other Backward Classes”; such reservations have been extended to a variety of groups in most Indian states and, since the 1990s, at the national level.

Wherever they have been implemented, affirmative action policies have proven to be highly controversial, generating heated debate and, at times, mass demonstrations. Where proponents see such policies as a way of rectifying historical injustices and integrating marginalized communities into the life of the society, opponents see these policies as a kind of “reverse discrimination” that contravenes the principle of equal rights for all individuals.

In recent decades academic scholarship has begun to shed light on the actual consequences of affirmative action policies, bringing empirical evidence to bear on debates most often dominated by ethical and political considerations. The evidence makes clear that the direct beneficiaries of affirmative action policies are most often relatively privileged members of underrepresented identity groups, who are in the best position to take advantage of improved
access to desirable positions and resources. It has become increasingly clear that affirmative action does not compensate those individuals most disadvantaged by past injustices, nor does it redistribute effectively from rich to poor. But it does foster greater integration of the societal elite, which can serve to legitimate and energize democratic political institutions, to inspire members of marginalized groups, and to improve the performance of tasks where greater diversity among performers contributes to better quality of service for a diverse clientele. Simultaneously, however, affirmative action heightens attention to identity group status, which may exacerbate divisive identity politics.

AFRICAN AMERICAN STUDIES

African American studies (also called black studies, African and African American studies, Africana and Pan-African studies, and African diaspora studies) combines general intellectual history, academic scholarship, and a radical movement for fundamental educational reform (Alkalimat et al. 1977). From its inception the field has embraced the focus of academic excellence and social responsibility in a unique approach that addresses traditional issues of “town and gown.” Though born out of turbulence, the discipline’s ability to persevere since its formal establishment in university settings makes it a lasting testament to the legacy of the Black Power movement and the goals of a long list of black intellectuals dedicated to bringing the history and culture of African Americans into a place of prominence in the American academy.

The first concerted calls to break from disciplinary foci that ignored the culture and background of black people came during the 1930s at the annual meetings of the Association for the Study of Negro Life and History (now the Association for the Study of African American Life and History). Building on the efforts of W. E. B. Du Bois (1868–1963) and Carter G. Woodson (1875–1950), Joseph Rhoads (1890–1951) and Lawrence D. Reddick (1910–1995) called for black colleges to expand traditional departments. By the 1940s historically black institutions such as Howard University were offering courses within the traditional disciplines that addressed issues of black concern. Arturo A. Schomburg (1874–1938) joined the efforts of these early proponents of black studies with his enormous collection of materials documenting the black experience. The donation of the collection to the New York Public Library and his work as the curator of its Black Life Collection led to the establishment of the Schomburg Center for Research in Black Culture, hailed by the New York Times (May 11, 2007) as a “cultural anchor in a sea of ideas.”

Early twenty-first century formations of African American studies at historically white institutions emerged as institutional responses to the “black studies movement.” Once the numbers of black students at historically white institutions developed into a critical mass, the general unrest and civil rights movement of the 1960s fueled the dissatisfaction that often led to aggressive and violent expressions. Cornell, Howard, Michigan, Rutgers, and San Francisco State are a few of the institutions where students demanded that black studies curricula be instituted and black faculty be hired. This black studies movement led to the formation of programs, departments, institutes, and centers at numerous colleges and universities, thus marking the period as a moment of radical rupture in the evolutionary history of the discipline.

The establishment of the first department of black studies occurred under the duress of a student strike. At San Francisco State, 80 percent of the racially and ethnically diverse student body joined forces and “made or supported unequivocal demands” (Rooks 2006, p. 4). Similar strikes occurred at Howard (March 1968), Northwestern (May 1968), Cornell (April 1969), and Harvard (April 1969). San Francisco State responded to the demands with the appointment of Nathan Hare as the acting chair of the Department of Black Studies in 1969. Other universities followed this course, with James Turner at Cornell (1969), Andrew Billingsley at Berkeley (1969),
Ronald Foreman at the University of Florida (1970), Carlene Young at San Jose State University (1970), Herman Hudson at Indiana (1970), and Richard Long at Emory University (1970).

The establishment of black studies as a legitimate academic discipline required intense discussions over the direction the course of study should take. Some of the earliest texts, including *Introduction to Afro-American Studies* (Alkalimat et al. 1977), *Introduction to Black Studies* (Karenga 1982), and *All the Women Are White, All the Blacks Are Men, But Some of Us Are Brave: Black Women’s Studies* (Hull et al. 1982), represented the differing perspectives and were foundational beginnings for many departments. Although the application of knowledge from a non-Eurocentric perspective is essential to the diverse intellectual frameworks that constitute the field, Africology, an Afrocentric perspective, was principally established in the work of Molefi Asante. Other (often competing) perspectives—such as St. Clair Drake’s Pan-Africanist view, Maulana Karenga’s cultural nationalistic Kawaida theory, Abdul Alkalimat’s “paradigm of unity” and technologically focused eBlack studies, James B. Stewart’s concept of the field as a disciplinary matrix, Gloria T. Hull’s focus on black women’s studies, Manning Marable’s scholarly commitment to the assault of structural racism in the context of global capital, and Henry Louis Gates and Cornel West’s focus on cultural studies—make important contributions to the intellectual trajectories of the field. Black British cultural studies in the work of Stuart Hall and Paul Gilroy generate new flows of ideas of a decentered cultural region and add to the discourse on intellectual frameworks for studying the black experience. Key to the mission of black studies throughout its evolutionary stages is the application of knowledge to promote social change, and it is at the core of the diverse intellectual and methodological approaches to the field. As with most social science disciplines, black studies scholars continue to reexamine the field.

The differences within African American studies, though important to each proponent, are far less destructive than many detractors suggest and provide evidence of the vibrancy and necessity of the discipline. Rather than leading to the demise of the field, diversity broadens and results (along with myriads of local community organizations) sometimes signals their intellectual trajectory, programmatic foci, and institutional mission.

The value and success of African American studies can be determined by its contribution to the transformation of higher education. The commitment to blending scholarship and activism instituted by most programs of study is reflected in different ways in other disciplines. The conditions under which feminist studies, ethnic studies, postcolonial studies, gay and lesbian studies, and cultural studies could articulate their positions were established by the introduction of African American studies into the academy.

Important to the continued development of the field are the many organizations and institutions that support African American studies. In addition to repositories such as the Schomburg, the Association for the Study of African American Life and History (ASALH), the National Council of Black Studies (NCBS), the Association of Black Cultural Centers, and eBlackstudies.org are among a number of organizations dedicated to the gathering and dissemination of knowledge on the black experience. Through their meetings, journals, and public programs, these organizations (along with myriads of local community organizations and dedicated scholars) continue to address the diverse challenges facing black studies and the social sciences in the twenty-first century.

African Americans

Marilyn M. Thomas-Houston

AFRICAN AMERICANS

The term African American has typically referred to descendants of enslaved and indentured black Africans transplanted by force into what is now the United States. The terms African American, black, and Afro-American are sometimes used interchangeably. African American has supplanted other designations, such as Negro, derived from the word Negroid, coined in the eighteenth century by European anthropologists. African American is sometimes applied more broadly to descendants of all ten million or more Africans forcibly transported to the Western Hemisphere from the beginning of the sixteenth century until the 1860s.

Africans shipped to the United States represented over forty ethnic groups from twenty-five different kingdoms, but constituted only 7 percent of all Africans transported to the Western Hemisphere by 1810. Over time, their descendants in the United States formed a composite identity shaped primarily by shared conditions, since historical circumstances and systematic de-Africanization efforts precluded the tracing of ancestry to precise points of origin. African American identity has been and is continuing to be constructed out of an African cultural and historical legacy, but is shaped within the framework of intragroup cooperation and intergroup conflict within American society.

Chattel slavery contributed significantly to pre–Civil War economic growth in the United States. The invention of the cotton gin (1793) dramatically increased the demand for slaves by lowering the cost of cotton production and inducing landowners to expand production beyond coastal areas. Approximately one million African Americans were redeployed from the upper to the lower South via a well-organized urban-based internal slave trade. Slavery was a normal feature of southern American cities—in 1860 there were approximately seventy thousand urban slaves. Exploitation of African American labor resulted in a massive increase in cotton production from 300,000 bales in 1820 to nearly 4.5 million bales in 1860. Plantation owners used harsh physical punishments such as whippings, brandings, and amputations along with incentives to garner compliance. Incentives included prizes for the largest quantity of cotton picked, year-end bonuses, time off, and plots of land. Developing reliable estimates of income and wealth generated by slavery is difficult because much of the accumulated wealth of the slave regime was destroyed by the Civil War. Some income financed planters’ conspicuous consumption, a portion was converted into personal wealth holdings, and another fraction provided capital for large-scale industrial ventures.

A dramatic disparity in wealth holdings between African Americans and white Americans constitutes one of the most enduring legacies of slavery. While emancipation enabled African Americans to increase the portion of income actually received from agricultural pursuits, forces reproducing wealth disparities ensured continuing subjugation. The arrangements by which most African Americans remained tied to the agricultural sector were characterized as the “tenancy system.” Three different classes of tenancy emerged: cash tenancy, share tenancy, and sharecropping. Sharecroppers, the status to which African Americans were disproportionately relegated, owned nothing. Implements were supplied by the landowners on credit and the sharecropper paid half the crop as rent to the landowner. Debt peonage emerged when the croppers’ share of the harvest was insufficient to repay the landlord. Landlords often charged exorbitant interest rates for supplies and failed to give croppers their full share of the harvest value. Sharecropping laws required that indebted croppers remain on landlords’ land until all debts were satisfied.

Prior to World War I (1914–1918), African Americans remained overwhelmingly rural residents. In 1910 over 90 percent of the 9.8 million African Americans lived in the South and only 25 percent lived in cities of 2,500 or more. Between 1890 and 1910 the percentage of African American males employed in agriculture fell only slightly; the occupational situation of females actually worsened. The persisting effects of institutional discrimination introduced during earlier periods led to an unusual set of circumstances whereby the occupational and economic status of African Americans declined as their absolute and relative education was increasing. The opposite pattern would have been predicted by traditional economic models. Moreover, the trends in inequality that developed during this period were reproduced into the 1980s.

Spurred by floods, crop destruction by boll weevils, and the need for workers in war-related industries, the
first net exodus from the South of about 454,000 African Americans occurred between 1910 and 1920. During World War I, the Division of Negro Economics was established within the U.S. Department of Labor to reduce tensions resulting from the introduction of African American workers into northern factories. The wisdom of this initiative was reinforced by race riots in Chicago, Omaha, and Washington, DC, during the summer of 1919.

Northward migration initiated a redefinition of African American identity that manifested itself most visibly in the cultural movement termed the “Harlem Renaissance” and the associated concept of the “New Negro.” The negritude movement that developed in the French African and Caribbean colonies introduced similar reconceptualizations of black identity. The African American scholar Alain Locke (1886–1954) declared that this redefined identity reflected a transformation in psychology such that “the mind of the Negro seems suddenly to have slipped from under the tyranny of social intimidation and to be shaking off the psychology of imitation and implied inferiority” (1925, p. 631).

Efforts to translate this new sense of identity into economic gains proved, however, to be problematic. Throughout the interwar period, rapid technological change increasingly pushed African Americans out of the agricultural sector. By 1930 the percentages of African American males and females employed in agriculture had fallen to 45 percent and 27 percent, respectively. Opportunities for manufacturing employment for African Americans were largely restricted to nonunionized industries, prompting a resurgence of self-organizing efforts, such as those of the Brotherhood of Sleeping Car Porters, formed by the labor leader A. Philip Randolph (1889–1979).

Many African Americans capitalized on the new industrial employment opportunities generated by World War II (1939–1945), and this prospect contributed to a net southern out-migration of 1.6 million between 1940 and 1950. Between 1910 and 1950 the proportion of African American males employed as operatives increased from 6 percent to 22 percent. By 1950 the proportion of African American males and females employed in agriculture had fallen to 25 percent and 10 percent, respectively. For African American women, the decline in agricultural employment was associated with increases in employment as service workers, operatives, clerical and sales workers, and private household workers. These employment shifts contributed to a marked improvement in African Americans’ economic progress after World War II. Even before the civil rights movement took center stage in 1956, one in every three urban African American families owned their own home.

The civil rights and Black Power movements signaled shifts in the political and economic consciousness of African Americans catalyzed, in part, by the emergence of a larger and more diverse middle class. The two movements offered different approaches to addressing identity and economic advancement issues. The civil rights movement promoted complete integration of African Americans through elimination of all legalized segregation and discrimination, whereas the Black Power movement emphasized group solidarity and self-determination. It is important to note that the ideologies undergirding these movements were influenced significantly by such Caribbean scholars as Frantz Fanon (1925–1961), C. L. R. James (1901–1989), and Eric Williams (1911–1981), as well as the liberation movements that developed in the African colonies. The most concrete policy outcomes of the civil rights movement were the Civil Rights Act of 1964, the Voting Rights Act of 1965, and the Equal Housing Act of 1968. Measures focusing on redistribution of economic benefits, such as affirmative action, have proved to be more controversial and less successful.

While nondiscrimination and affirmative action policies have undoubtedly contributed to increases in the relative income of African Americans, as well as significant improvements in occupational distribution, many African Americans have not experienced significant improvements in economic well-being. Moreover, data covering the mid-1990s to the first decade of the twenty-first century paint a fairly consistent picture of racial wealth disparities—namely, that the wealth of African American families is less than one-fifth of that of whites. Stagnation in the quality of life of many African Americans has resulted, in part, from disproportionate vulnerability to forces associated with transformation of the U.S. economy. Between 1960 and 2000, the percentage of men working as operatives, fabricators, and laborers has declined from 46 to 29 for African Americans and from 25 to 18 for white Americans. About 50 percent of all workers displaced as a result of plant closings and relocations had been employed in manufacturing, and African Americans have been significantly overrepresented among displaced workers. In the wake of these employment shifts, African American men have a much higher unemployment rate than other groups, and between 1991 and 2000 the percentage of African American men not in the labor force has averaged 26, compared to 15 for whites.

Black Power ideology emphasizes African American self-determination, economic self-sufficiency, and black pride; these foci became a catalyst for the displacement of terms like Negro and colored. Black and Afro-American were in vogue briefly, but African American became the most popular term during the 1980s. Advocates of African American argue that this term is consistent with
the nation’s immigrant tradition of “hyphenated Americans,” which preserves links between people and their or their ancestors’ geographic origins. For many, African American describes cultural and historical roots and also conveys pride and a sense of kinship and solidarity with other African diasporans.

Embracing the designation African American is not symbolic of a commitment to the type of cultural nationalism advocated by Black Power proponents. This is especially the case in the economic arena, although some contemporary commentators claim that African Americans’ disposable income constitutes a potential form of collective economic power, an argument reminiscent of those advanced in the past. However, suburbanization of a significant segment of the black middle class has stymied efforts to promote any functional type of economic development in the black community, which would require, among other conditions, the capacity to exercise sufficient control over economic resources to mobilize production processes and create markets.

Ironically, African American suburbanization has also not produced outcomes anticipated by integrationists, such as substantial reductions in residential segregation. Like their inner-city counterparts, African American suburban dwellers experience a high degree of residential segregation. In addition, middle-class suburbanization has increased the isolation experienced by inner-city African American residents, and has made it increasingly difficult to ameliorate persisting economic and social inequalities. The economic prospects of inner-city African American residents are constrained, in part, by a spatial mismatch between job location and place of residence as African Americans generally have the longest travel times to work in all regions of the country where public transportation is available.

Divergence of interests between middle-class and other African Americans creates new complications in defining African American identity. Each group accesses different configurations of “social capital,” that is, the complex of resources associated with group membership that individuals can use to enhance well-being. Persisting differences in social capital can generate disparate conceptions of group identity. Conventional notions of African American identity are also challenged by phenotypical discrimination reminiscent of patterns associated with the one-drop rule operative during the slavery and Jim Crow eras that led to formal designations of the extent of African parentage—mulatto (1/2), quadroon (1/4), and octrooan (1/8).

Phenotypical discrimination results in African Americans and Latinos with the darkest and most non-European phenotype receiving lower incomes, having less stable employment, and obtaining less prestigious occupa-

African Crisis Response Initiative

The African Crisis Response Initiative (ACRI) is a program that the United States launched in 1996 to address challenges of peacekeeping and conflict management in Africa. Its formation was prompted by fears that the ethnic massacres that occurred in Rwanda in 1994 might also take place in neighboring Burundi, and by the desire of the United States to avoid getting entangled in local conflicts, as occurred in 1993 when eighteen U.S. Army rangers were killed in Somalia, where the United States had intervened to provide humanitarian assistance.

Initially, the United States wanted to establish an African force that could intervene to save lives in humanitarian crises. After consultations with numerous African and non-African officials, the United Nations, and the Organization of African Unity (OAU), the U.S. government decided to establish a program to build such a capacity among African militaries.

ACRI was established to enable selected African military forces to respond to crises through peacekeeping missions in Africa. The initiative aimed at training and equipping African peacekeepers as rapid-response contingency forces that could be quickly assembled and deployed under the auspices of the United Nations, the OAU, or subregional organizations. Participation in peacekeeping missions depends on decisions at the national level. U.S. special forces soldiers conducted the training on common peacekeeping doctrines and procedures. African militaries were trained in basic soldiering skills at individual, squad, platoon, and company levels.

AFRICAN CRISIS RESPONSE INITIATIVE

James B. Stewart
The selection criteria for countries participating in ACRI raised questions about U.S. interests. Such an initiative carries the risk of dividing states into those that are considered pro-American and those that are not. It also risks undermining local initiatives for conflict resolution. Countries participating in the program had to have democratic governments and professional militaries with a record of previous peacekeeping. Uganda and Ethiopia did not pass the test, but were selected to participate in the initiative. Several countries that were initially considered for participation became ineligible. Follow-up training was suspended in Ethiopia, Uganda, and Côte d’Ivoire in 1998. Ethiopia was embroiled in a war with Eritrea, as was Uganda in the Democratic Republic of Congo. Côte d’Ivoire had experienced a military coup and was facing civil strife.

ACRI partners contributed to conflict resolution in Africa. Mali and Ghana sent forces to Sierra Leone as part of the ECOMOG (Economic Community of West African States Cease-Fire Monitoring Group) peacekeeping force. Benin provided a contingent to Guinea-Bissau as part of ECOMOG, and Senegal contributed troops to the UN mission in the Central African Republic. The success of ACRI was undermined by the lack of an institutionalized security framework within which it could operate. An African continental security framework for conducting peacekeeping is in its infancy, while subregional security frameworks like ECOMOG and SADC (Southern African Development Community) that have participated in peacekeeping operations are fragile. Programs like ACRI also risk contributing to the militarization of conflicts by strengthening the militaries of conflict-ridden countries and regions. It is likely that the participation of some states in ACRI was motivated by the need to strengthen their militaries to deal with internal and regional conflicts rather than a desire to engage in peacekeeping.

The African Contingency Operation Training and Assistance (ACOTA) program succeeded ACRI in 2004. ACOTA focuses on training military trainers and equipping African militaries to conduct peacekeeping support operations and to provide humanitarian relief.

BIBLIOGRAPHY

African Diaspora

The African diaspora was the dispersal of African peoples to Asia, Europe, and the Americas. The term is used most commonly for the coerced movement in various slave trades, but the word diaspora has also been used to refer to voluntary migrations from Africa and for population movements within Africa.

In some ways, the most consequential movement of peoples from Africa was the first, when the early stages of human evolution took place in the highlands of East Africa. From there, over the last million and a half years, human beings spread out across Africa, gradually adapting to different environments, and then into Asia, Europe, and eventually the Americas. More recent large-scale movements of peoples have occurred within Africa. For example, over the last 2,500 years, people speaking Bantu languages have spread out from a base in the Nigeria-Cameroon borderlands over most of southern and central Africa, absorbing most preexisting populations.

THE EMERGENCE OF A MARKET FOR SLAVES

Almost six thousand years ago, complex civilizations marked by powerful imperial states began emerging in the alluvial valleys of Mesopotamia, then in Egypt and India. These were slave-using societies, though not as dependent on slave labor as some more recent societies. They were also involved in long-distance trade. They tended to obtain their slaves from warfare, from trade with less-developed neighbors, and through debt and social differentiation. Athenian Greece, the first real slave society, acquired slaves from the Balkans, the Black Sea areas, and Asia Minor. There was, however, from an early date some movement of Africans into these worlds both as slaves and free persons. Egyptians were involved in conflict with Nubia and were ruled by dynasties from the south. Nubia, and perhaps the Horn of Africa, were sources of Egyptian slaves, though slaves also came from many other groups. Statuary and paintings from ancient Egypt clearly indicate the presence, sometimes as rulers, of people with African physical features. There were certainly Africans elsewhere in the Mediterranean world. Authors of the Old Testament and from classical antiquity were clearly familiar with Africans. Trade across the Indian Ocean was also taking place at least two thousand years ago, and clearly involved some movement of people, both free and slave.

The emergence of Islam in the seventh century and the subsequent conquest of the Middle East and much of the Mediterranean world expanded the market for slaves. Although Islam forbade the enslavement of fellow Muslims, it also created a demand for slaves, particularly as concubines, servants, and soldiers, but also sometimes as laborers. There was, for example, a major revolt in
ninth-century Mesopotamia among the Zanj, East African slaves who were subject to harsh labor draining the swamps of lower Mesopotamia. Exploitation of African slaves seems to have been rare, however. The Muslim empires got most of their slaves from eastern Europe and the Caucasus, as did the Christian cities of southern Europe. For the Muslim Middle East, eastern Europe remained the most important source of slaves into the eighteenth century.

A trade in slaves with Africa, however, remained significant. Christian kingdoms in the middle Nile region paid a tribute to Egypt, which was partly in slaves. Ethiopia seems to have sold slaves to Muslims. The introduction of camels in the first centuries of the Common Era increased trade across the Sahara; trade was further increased when Arab conquerors revitalized the Middle East. The trans-Sahara trade led to the emergence of Muslim states in the savanna belt known as the Sudan, which comes from the Arabic *bilad-es-sudan,* "land of the blacks." For many of these Sudanic states, slaving became a source of labor and services, as well as an export that could be exchanged for Middle Eastern products. For Ghana, Mali, and Songhai, the export of slaves supplemented a trade in gold, but for Kanem and Bornu in the central Sudan, slaves were the major export. Slaves were probably less important to the Swahili cities of the east coast, though they were a constant export.

African slaves from Ethiopia and East Africa served as soldiers and concubines in India. In 1459 there were supposedly eight thousand Africans in Bengal’s army. A number of African military commanders became rulers of small states, of whom the best known was Malik Ambar (d. 1626), who was noted for his tolerance and his patronage of the arts. Communities of people of African descent known as *Habshis* or *Sidis* are still found in India and Pakistan. There were also African merchants and sailors in India.

Africans could also be found, in different roles, in many parts of the Arab world. There were, for example, a succession of poets in pre-Islamic and early Islamic Arabia known as the “black crows.” One of the companions of the Prophet Muhammad (c. 570–632) was an African, Bilal, who served as the first *muezzin* for the Muslim community. In the Muslim empires, particularly that of the Ottoman Turks, black eunuchs were common. They played an important role in the Ottoman harem. African slaves were particularly important in Morocco and Tunisia and provided much of the labor in the mines and oases of the Sahara. Some scholars have estimated that African slave exports into the Middle East were as numerous as those across the Atlantic. They did not, however, leave as deep a footprint. Most were women who became concubines. As concubines, they produced few offspring and those offspring were free members of their masters’ families. Soldiers probably experienced high mortality and thus left behind few identifiable communities. As a result, few self-reproducing African communities developed in the Arab world.

**THE ATLANTIC SLAVE TRADE**

The Portuguese ships that cruised along the African coast were not primarily interested in slaves, but slaves could be procured. The first were taken in raids, but trade soon proved more effective. Slaves could be purchased from many African societies, and the profits from the slave trade helped pay for many early expeditions. Some slaves were exchanged within Africa—for example, for gold along the Gold Coast—but most were sold in Portugal or at Mediterranean slave markets where a shortage of slaves developed after the Ottoman conquest of Constantinople in 1453 limited Mediterranean access to eastern European slaves. African slaves became important in Lisbon, southern Portugal, and Mediterranean cities.

A more important market soon developed on the Atlantic islands, which had become underpopulated or depopulated when earlier populations were decimated by slavery and by European diseases, though many islands, like Madeira, had no native population at all. Sugar was the key to their prosperity and to the development of a particularly harsh slave system. Venetian and Genoan planters had begun the exploitation of sugar in the eastern Mediterranean during the Crusades. As improved technology reduced the cost of producing sugar, an expanding European market offered large profits, and the Atlantic islands offered European investors an opportunity to extend sugar cultivation. Madeira was briefly the world’s largest sugar producer, and then São Tomé. On Madeira and in the Canaries, both slave and peasant labor was used, but the equatorial climate of São Tomé made the island unattractive to European peasants, and a plantation system developed there that depended exclusively on slave labor. In the late sixteenth century, this plantation system was extended to Brazil, where once again, the decimation of Indians by European diseases led to the use of African slave labor. The plantation model was extended to the West Indies in the seventeenth century.

The use of slaves was attractive wherever labor was in short supply and new crops offered prospects of profit. Slave labor produced rice in South Carolina and tobacco in Virginia. Slaves were also used to grow indigo, spices, and coffee. Slaves were found everywhere in the Americas and were important even in the Middle Atlantic colonies. The availability of slaves meant that they could be acquired for many purposes. They worked as servants; they worked on the docks; and after the invention of the cotton gin they provided the labor for the extension of
cotton over the southeastern United States. Sugar, however, created the biggest market for slaves.

Slave exports grew from about a quarter million in the sixteenth century to over six million in the eighteenth. Only in what became the United States did natural population growth among slaves eventually make the slave trade irrelevant. As native slaves either died out or were absorbed into an African population, slavery came to be seen as the lot of the African. This is probably the first time that enslavability was defined in terms of race.

To meet the steadily increasing demand, slave traders pushed routes deeper and deeper into the interior of Africa. Prices rose, old states were militarized, and new states appeared that were willing to provide the slaves Europe wanted. The late seventeenth and early eighteenth century saw the emergence of a series of powerful slaving states that responded to rising prices and demand in the West Indies. A smaller slave trade emerged in East Africa after islands in the Indian Ocean were colonized. The conquest of what is now the Ukraine by the Russians closed off the major source of white slaves in the late eighteenth century. Increasingly, during the last years of the international slave trade, the Middle East looked to African sources for their slaves. The East African slave trade was also stimulated by the development of a plantation economy in Zanzibar and on the East African coast, as well as economic growth in the Middle East.

THE WORLD OF THE DIASPORA

Many of the early sugar planters treated slaves as expendable. Sugar was a particularly brutal crop, and slaves worked long hours under abusive conditions. The mortality rate, particularly for men, who did the most dangerous work in pressing and boiling rooms, was high. For planters, it was often easier to buy a slave than to raise one, and many early planters literally worked slaves to death. With time, however, family life developed because planters found that slaves worked better when allowed to live in family relationships. Though mortality remained high until the end of the slavery era, the ratio of men and women gradually moved toward parity.

Family life and natural reproduction among slaves developed much more quickly elsewhere. In the tobacco areas of Virginia, the slave population had been growing since the 1720s. Slave culture was shaped by the beliefs and culture that slaves brought with them from Africa, by the conditions of slavery, and by the world of their masters. The perpetuation of slave culture was influenced by the identification of slave status with African origins. In the European world, color became an important boundary that persisted even when slaves were freed.

African roots show especially vividly in religions. Throughout the diaspora, we find religious cults of African origin: candomblé in Brazil, shango in Trinidad, Santeria in Cuba, vodou in Haiti, gnawa in Morocco, bori in Tunisia, and zar in Istanbul and southern Iran, all of them involving spirit possession and the use of music. Like the African systems from which they emerged, these cults assimilated elements of dominant religions, but also in many cases influenced those religions. This is most striking in the United States, where the African impact is found less in distinctive cults than in the way Africans shaped the practice of Christianity, particularly among Baptists. African religious practices, like the ring shout, led to a highly emotive and richly musical practice of Christianity among African Americans. Similarly, in Hindu and Muslim parts of the world, Africans were absorbed into the dominant religion but often infused it with an African approach.

African musical traditions are also prevalent throughout the diaspora: the drumming of sides in India, gnawa music in Morocco, Afro-Cuban music, and calypso in Trinidad, as well as gospel, blues, and various kinds of jazz. These different traditions have taken on a life of their own and feature a variety of musical instruments, but all have African roots. So too with language. The grammatical structure of African languages often shaped the development of pidgin languages, and African terms became a source of slang. In Maroon communities, formed by runaway slaves, African political traditions also shaped the states that were created. Some scholars see the African family structure in the kind of extended and often fictive family that evolved in the slave quarters and protected Africans from the insecurity of slavery, where a family member could be sold off at any time. African folklore and African craft skills, such as pottery or raffia work, also remained important in many diaspora communities.

FREE MIGRANTS

Not all Africans migrated in chains. Many free migrants traveled within and from Africa, including those who went to Morocco, Egypt, or the Arabian Peninsula to study at Islamic institutions. Many medieval African rulers made the pilgrimage to Mecca, and some supported hostels for their subjects who were studying at Muslim schools. Some of these travelers stayed and married. Africans also migrated to Europe. Missionaries brought Africans to Europe to study, some of whom returned to Africa. Others came as ambassadors. Free Africans also worked on oceangoing vessels in both the Indian Ocean and the Atlantic. The Kru in Liberia, for example, developed a tradition of working on European vessels. By the eighteenth century, there were small populations of free Africans in many major port cities of Europe, the Americas, and the Middle East. In the nineteenth century, the Soninke of the upper Senegal River
area moved from working on riverboats to hiring on to oceangoing vessels. Most went home, but many settled in port cities of Europe.

These migrations increased with the end of slavery, particularly the migration of Africans who traveled to get an education. In the early twentieth century, there were about one hundred South Africans studying in the United States and more in Europe. The establishment of colonial rule also made it easier for Muslim Africans to travel, both for the pilgrimage and to seek an education. During the colonial period, most African migration took place within Africa, but there were also migrations from parts of the diaspora. Jamaicans, for example sought plantation work in Central America and Cuba, and some people from the West Indies immigrated to the United States and England. The number of Africans in North America and Europe increased significantly after World War II (1939–1945); this population was spearheaded by students but also included working-class economic migrants.

There was also a process that Michael Gomez calls “reconnection,” as some from the diaspora went back to Africa. Edward Blyden from the Virgin Islands, for example, became an influential intellectual in nineteenth-century Sierra Leone and Liberia. In addition, missionaries from black churches in Europe and the Americas, particularly the African Methodist Episcopal Church, took Christianity to various parts of Africa. A sense of having roots in Africa was more important to diaspora intellectuals than to those who remained in Africa. Five Pan-African congresses were held between 1900 and 1945, only the last of which included major African participation. Marcus Garvey (1887–1940) organized a “back to Africa” movement, and diaspora intellectuals in France developed the literature of négritude.

Migration increased dramatically after independence came to most of Africa in the 1950s and 1960s. Increasing numbers of African students sought higher education abroad during the postindependence period, and African workers started going to Europe and then to North America. Some fled oppressive political conditions, while others left because their home countries’ stagnant economies offered them little future. Today, many highly skilled African professors, engineers, and scientists emigrate to better use their skills and achieve a more comfortable life. The Mourides, a Muslim religious fraternity in Senegal, have helped organize the emigration of people who work as street vendors. In the cities of Europe and North America, the different branches of the diaspora are merging, the newest migrants from Africa joining migrants from the West Indies and an indigenous population of African descent. By the beginning of the twenty-first century, these migrations, particularly of unskilled workers, were beginning to meet resistance in Europe.

AFRICAN NATIONAL CONGRESS

The origins of the African National Congress (ANC) were a conference of black South African notables assembled in 1912 to protest impending legal restrictions on African land ownership. Until the 1940s, the ANC remained decorously circumspect: lobbying, submitting memorandums, and relying heavily on white liberal intermediaries. During World War II (1939–1945), the ANC began to build a mass membership structure and attempted to mobilize popular support by contesting local “advisory board” elections in black townships. By this time, several of its leaders were also members of the Communist Party. Communists had initially concentrated on winning white worker support but switched their efforts to blacks in the late 1920s.

Within the ANC, both communists and a group of young self-professed “Africanists” who formed a Youth League helped to influence the ANC to embrace more
aggressive tactics. It adopted in 1949 a “Program of Action” calling for strikes, boycotts, and civil disobedience as means toward a goal of African “self-determination.” The ANC’s radicalization coincided with the accession to government of the (Afrikaner) National Party (NP). In power, Afrikaner nationalists began to tighten and extend racial segregation policies. In practice, the NP’s apartheid policies sought to confine black participation in the urban economy to unskilled and semiskilled labor.

The Communist Party was banned in 1950. Thereafter its members would work within the ANC. Communist influence as well as older liberal traditions instilled by the Methodist schools that trained most African political leaders ensured that although the ANC itself remained an exclusively African body, it defined its program on a broader basis. It sought allies in the Indian Congress movement, founded in Natal by Mohandas Gandhi in 1894, and in 1952 encouraged the establishment of a Congress of Democrats for white sympathizers.

The ANC’s Freedom Charter, adopted in 1956, referred to a democratic future in which all races would enjoy equal rights. In 1952 a “Defiance Campaign” against new apartheid laws failed to win any concessions but succeeded in swelling membership to 100,000. Six subsequent years of mass-based militant resistance helped to convince a number of ANC principals, including its patrician but popular deputy president, Nelson Mandela, that the organization had exhausted the available options of peaceful protest. A breakaway movement, the Pan-Africanist Congress (PAC), formed in 1959 as a more radical alternative. The Pan-Africanists emphasized African racial identity and criticized the role of the Communist Party in “watering down” the ANC’s nationalist predispositions. In fact, the Communist Party’s influence was most evident in the mild socialism of the Freedom Charter. In 1960 the PAC committed itself to resisting the pass laws. In Sharpeville on March 21, outside Vereeniging, police were confronted by a crowd of five thousand people, and the tense standoff culminated with the police firing and killing eighty. In the national tumult that followed, the government banned both the PAC and the ANC. The ANC reconstituted itself underground and in 1961 formed an armed wing, Umkhonto we Sizwe (Spear of the Nation). In 1963 Umkhonto’s high command was arrested and most of its members sentenced to life imprisonment for their leadership of a sabotage campaign.

For the next thirty years, under the leadership of Mandela’s close professional associate and friend, fellow ex–Youth Leaguer and attorney Oliver Tambo, the ANC would base itself in Dar es Salaam and Lusaka. Only in the mid-1970s could it begin rebuilding its clandestine organization in South Africa. In exile, the ANC strengthened its alliance with the Communist Party, and in stages between 1969 and 1985 it opened its ranks to whites, Indians, and coloreds (in South Africa, any person of mixed racial descent). Survival in exile required discipline and authority, and communist organizational models were influential. Today, Leninist tenets of “democratic centralism” remain in the organization’s constitution. After 1976, ANC guerrillas succeeded in attracting public attention with bold attacks on symbolic targets. So-called armed propaganda brought the ANC considerable public support both in South Africa and internationally, though Umkhonto’s campaigning hardly represented a serious military threat to white security.

Meanwhile a charismatic cult developed around the imprisoned leaders on Robben Island, especially Nelson Mandela. Mandela’s stature was a key factor in achieving for the ANC the degree of recognition or acceptance it enjoyed outside communist countries: By the late 1980s meetings between its leaders and Western statesmen served to underline its status as a government in waiting. The military command structure controlled the destinies of most of the refugees who joined the ANC after 1976. In this part of the organization communists were especially powerful.

However, around its foreign missions and its own educational establishment the ANC began to foster a group with administrative and technical skills, many of its members the recipients of U.S. and western European higher educations. Members of this group began to develop policy blueprints for a post-apartheid liberal democracy. From within this community the ANC also began to make the first cautious moves toward a negotiated settlement in the mid-1980s, a process in which Thabo Mbeki, the head of the ANC’s directorate of international affairs, was a principal actor. Separately, from inside prison, Nelson Mandela began his own program of meetings and conversations with senior government officials and cabinet ministers. In February 1990 the South African government repealed its prohibitions of the ANC and other exiled organizations.

Ironically, the ANC’s development over thirty years as a virtual government in exile was the key to its successful reentry into the domestic terrain of South African politics. The international recognition it received brought with it the financial resources needed to build a mass organization in South Africa of unprecedented scope and sophistication. This organization would not only absorb the exile “liberation bureaucrats” and returning soldiers but also bring together a variety of movements that had developed inside South Africa during their absence, including some of the homeland-based political parties and the vast federation of civic bodies led beginning in 1983 by the United Democratic Front.
Between 1990 and 1994 the ANC played a decisive role in negotiating a fresh constitutional dispensation. After elections in 1994, Nelson Mandela would lead a transitional Government of National Unity in which the ANC would share power with its old adversary, the National Party. The ANC won successive electoral victories in 1999 and 2004.

In power, the ANC’s market-friendly economic policies, encapsulated in the GEAR (Growth, Employment and Redistribution) program, have reflected leadership concerns about retaining and attracting investment capital. The rewards of economic liberalization have included increases in GDP (currently around 3.5%) and a measure of white support especially after former National Party leaders joined the ANC and Thabo Mbeki’s government in 2003. The government has also been successful in promoting a black business class. The ANC’s continuing popularity is probably more a consequence of expanded access to pensions and grants. More equitable provisions are unlikely to guarantee that the ANC will hold its political base for very much longer. Free-market policies have failed to check social inequality or unemployment. After more than a decade in office, the ANC today is sharply divided to check social inequality or unemployment. After more than a decade in office, the ANC today is sharply divided.

AFRICAN SOCIALISM

SEE Socialism, African.
There are both Eurocentric and Afrocentric versions of Africa prior to European contact. The most extreme Eurocentric versions are of “primitive” (and “backward” and “uncivilized”) “tribes” and worse—the “Niam-Niam” who had tails, according to Count de Castelnau’s 1851 book *Trogloïdtes*, inhabiting caves and hunting unicorns (Rigby 1996). Spurious claims concerning “Hamitic” and “Caucasoid” Africans accompanied the attempts to de-Africanize ancient Egypt. The African-centered versions focus on ancient Egypt (Kmet) and Ethiopia and the empires of Ghana, Mali, and Songhai in the West and the Zimbabwe, Monomotapa, and Rozwi kingdoms in the South (Williams 1974; Du Bois 1965). Of course there are both oral and written indigenous African and Afro-Arab literatures and histories, including the writings of Ibn Khaldun and Ibn Battuta and works such as *Sundjata: An Epic of Old Mali* (Niane 1965). Since not all whites or Europeans are Eurocentric and not all black or African scholars are Afrocentric, the issues are not at all easy to disentangle. In addition African studies is not simply another branch of an “area studies” curriculum that would include Asia, Latin America, and so on. Each has its own unique history and motivations driving its research. There are also important methodological issues at stake in the various debates. These came to the fore especially during the struggles that gave rise to black studies programs, in many cases resulting in departments and programs that combine African and African American studies, such as Africana, Pan-African, and black global studies programs.

There are Euro-centered frameworks that supported African liberation or that reject race as a biological or natural category, including many Marxian approaches to African studies (of particular note are the French structuralists, e.g., Bonte 1975, 1981). There are on the other hand a variety of African-centered paradigms, some of which reject Marxism, and some that do not necessarily reject the idea of race. A number of periodizations of African studies have been put forward (e.g., Copans 1977; Temu and Swai 1981; Moore 1993), and they are in general agreement concerning colonization, decolonization, and the post-political independence periods, the latter dominated by neocolonialism and imperialism. In the face of ongoing crises on the continent (civil war, famine, epidemics, and so forth), the 1990s saw a surrender to an “Afro-pessimism” (Hyden 1996) that ignored many important victories, large and small, from the end of apartheid in South Africa to the successes of grassroots organizations (e.g., the Green Belt movement).

Postcolonial approaches (Eze 1997) combine materialist and discursive components into an analysis that rejects determinist Marxism, while their qualms about the Afro-centered frameworks are concerned more with the “centrist” part than the African. Just as distinctions must be made between liberatory and fascist nationalisms, one may utilize Afrocentricity in a “strategic essentialist” fashion. In addition a wave of “Afro-Oriental” approaches have been increasingly appearing, going back at least as far as the Bandung Conference of 1955, promoting Afro-Asian unity and international anticolonialism based on the common historical experiences of colonialism and racism while respecting the integrity of cultural differences (e.g., Mullen 2004). “African womanism” offers a wide range of uniquely African-centered feminist perspectives (e.g., Dove 1998). These encouraging developments are examples of the vitality, originality, and creativity of African studies in the twenty-first century.

Africville (Canada)

Africville has correctly been called Canada’s most famous black community. It has been the subject of books (both scholarly and fiction), award-winning documentaries, thousands of newspaper articles (local, national, and international), hundreds of graduate student theses, poems, songs, a jazz suite, symposia, and an exhibition that traveled across Canada and is now housed permanently at the Black Cultural Centre in Halifax Regional Municipality in Nova Scotia. There remains a continuing negotiation between the city of Halifax and the Africville Genealogical Society, which speaks for the former residents of Africville and their descendants, over compensation for the people of Africville and proper recognition of the community. A United Nations committee has also weighed in on the importance of Africville, the significance of its history, the racism and neglect that eventually made its people vulnerable to the urban renewal process and relocation, and the validity of the Africville Genealogical Society’s claims for compensation and recognition. Virtually all the public attention, certainly all the positive characterization, has occurred in the years since the community buildings were bulldozed out of existence and the residents scattered, mostly into neighboring areas of the former seashore site. Africville no longer exists in a physical sense, though surviving members and their descendants and friends usually gather each summer at the former site, now the Seaview Memorial Park, to renew ties, remember, and enjoy themselves.

Africville was founded by black refugees from the War of 1812 and their descendants, when blacks—some free, mostly slave—fled the United States for the promise of freedom and a better life in the British colony of Nova Scotia. Although not without some controversy, sociologists and historians have established that the first black settlers into the Campbell Road area of Halifax purchased their properties from white entrepreneurs in the 1840s. These first black families came from the areas of Preston and Hammonds Plains, where most of the refugees had settled, joining with loyalist blacks who had earlier fled the American Revolution (1775–1783). The move to Halifax was driven by economic need, since surviving on the small lots of scrubland made available to the refugees was difficult, if not impossible. Taking up a new life in the city, though at its outer peninsular edge, made possible both a bucolic lifestyle and opportunities for paid employment. The small community took hold over the next few decades with a church and a school. By the last decade of the nineteenth century, the name Africville had become...
Afrocentrism

widespread and the community was deemed by black leaders in Nova Scotia to be a fine community with much promise.

From the beginning of the Africville settlement, the community was constantly encroached upon by developments in the larger society. Land was expropriated for railway construction, and various facilities, such as sewage disposal pits and an infectious-diseases hospital, were established on the edges of the community in the nineteenth century, reducing the community’s residential attractiveness and signaling future intrusions. By the end of World War I (1914–1918), Africville was ringed by facilities rejected by other residential areas of the city and was largely left to fend for itself with respect to housing standards, bylaw enforcement, and policing. Residents petitioned for services but mostly to no avail. City officials claimed there was a minimal tax base there and in any event the Africville area might be better utilized for non-residential development.

Africville evolved as a small community with considerable social diversity, but increasingly its reputation suffered as small numbers of squatters and transients (often white) moved into the community from the 1930s on. The establishment of an open dump on its doorstep in the 1950s, in addition to its sometimes condemned wells and lack of paved roads, sealed its public image as “the slum by the dump.” It was a label that belied the community’s strengths and core respectable lifestyle, but one that was widely held in the larger society among both whites and blacks and that made it impossible to resist the pressures of urban renewal, liberal welfare relocation policy, and integrationist civil rights that emerged after World War II (1939–1945) throughout Canada and the United States.

When Africville residents were relocated in 1964 to 1967, the community’s population consisted of eighty households and about four hundred people. The relocation was hailed as a fine example of liberal welfare policy. The process was guided by proposals made by a leading Canadian social housing expert, with black and white representatives of an independent human rights commission involved in each relocatee’s settlement, and a social worker responsible for working with the residents and developing educational and employment programs. Within a few years, however, the relocation’s alleged success began to be sharply challenged as the promised benefits for many Africvilleans and their families were not realized. The educational and employment programs were minimal and ineffective; the housing conditions for many relocatees—public housing and housing in areas scheduled for redevelopment—left much to be desired; and the loss of community was much grieved.

Africville became a symbol of the need for black communities to appreciate their communal culture, build on their strengths, and resist similar pressures, and also of the hubris of a liberal welfare ideology that focused on individuals rather than communities and neglected the significance of social power in ensuring that promises become actualities. Africville became a symbol for the black community’s experiences in Nova Scotia, and the lessons learned perhaps a hope for its future.

AFROCENTRISM

Over the last three decades or so, the production, validation, legitimation, and mediation of knowledge about peoples African and of African descent were subjects of often very heated debate. A significant number of the generations of black academics, independent scholars, and teachers who came of age during the civil rights and black power movements became especially aggressive in their efforts to subject knowledge-production and knowledge-mediation to guiding norms of Afrocentrism. While many of the concerns now linked with Afrocentrism have older roots—for example, in the antiracist writings of W. E. B. Du Bois (The Negro, 1915; The Souls of Black Folk, 1903), the rehabilitative historiography of J. A. Rogers (World’s Great Men of Color, 1946–1947), and the works of George Washington Williams (History of the Negro Race in America, 1882)—the predominant steward of Afrocentrism in its modern form has been Molefi Kete Asante, of Temple University’s department of African American studies.

Asante’s call to become Afro-centric—that is, “African centered”—was shaped by twin forces: the politics of knowledge production, mediation, and appropriation, and resurgent black nationalism. The initial focus was on intellectual and political struggles over black studies; that is, on how to define, implement, and sustain systematic studies of black peoples (that is, Africans and peoples of

Donald H. Clairmont
Afrocentrism

Afrocentrism (and its evolving cognates Afrocentricity and Afrology) became a name with multiple references serving several related agendas. On one hand, it referred to epistemological and methodological norms and strategies by which to guide the production of knowledge by, about, and for black peoples. At the same time, the agenda was not merely scholarly: Afrocentric knowledge-production was to give guidance to history-making living in all dimensions of black life—political, sociological, and cultural.

Afrocentrism thus became a complex intellectual, social, political, and cultural movement with substantial impact on proponents and practitioners of black/African/Africana studies. While the Afrocentric orientation is by no means the only or even predominant guiding commitment, it has been an intellectual and political force to be reckoned with, especially by knowledge-workers of African descent. These scholars have felt compelled either to establish their Afrocentric credentials, or to declare their independence from or opposition to Afrocentrism. Furthermore, Afrocentric critiques of what has passed, and continues to pass, for knowledge about black peoples have compelled more than a few scholars, black and white, to undertake reviews and counter-critiques of their own. Moreover, the Afrocentric movement in the United States has spread well beyond college and university campuses and contestations among professional academics. It has challenged curricula and teaching in primary and secondary schools, with notable impact in a number of cities and states (Portland, Oregon, and New York state, for example).

In reaction to Afrocentrism’s influence, critics have posed a number of important questions: Do Afrocentric commitments render what is produced more ideology and propaganda than “objective truth”? Is Afrocentric knowl-

dge-work limited by the strictures of racialized epistemology and self-defeating methodological circularity? To answer these challenges, and to address Afrocentrism’s potential weaknesses, a number of scholars have sought to refine the concept. Asante has contributed to this refinement through his reworking of the concept of Afrocentrism as Afrocentricity in Kemet, Afrocentricity, and Knowledge (1990). So, too, has Maulana Karenga, in his Introduction to Black Studies (1993). And works by strenuous critics such as Stephen Howe (1998) and Mary Lefkowitz (1997), along with the work of disciplined and deft intellectual historians such as Wilson Jeremiah Moses (1998) have helped to foster healthy reconsiderations and refinements of Afrocentrism.

Irrespective of the excesses and deficiencies of the Afrocentric quest in its various guises, one core insight remains cogent: All modes of knowledge-production and mediation are “centered” on particular historically and culturally conditioned values and interests. Proponents of Afrocentrism have sought to make such interests, values, and commitments explicit in terms of the agendas and communities they serve, while disclosing the racist investments in whiteness and imperialism that have distorted so much of supposedly “interest-free,” “objective” knowledge-production and mediation.

Here, then, is Afrocentrism’s historic contribution: It has compelled us to become more mindful of, and honest about, our “centerings,” and, hopefully, inspired us to work much more openly and diligently for the achievement of a true “objectivity” free of the distorting limitations of invidious ethnocentrism and racisms.

AGENDA SETTING
Barbara Sinclair provides a concise definition of agenda setting: “the process through which issues attain the status of being seriously debated by politically relevant actors” (1986, p. 35). The study of agenda setting began as a reaction to the pluralist claim that policy outcomes are the result of competing groups (Dahl 1956, 1961; Truman 1951). E. E. Schattschneider (1960) claimed that groups would not necessarily form on both sides of an issue, given the upper-class bias in the system. Theodore Lowi (1979) highlighted this problem of imperfect competition, arguing that what gets on the congressional agenda is a process of bargaining between a few interested groups, elected officials, and administrators. Finally, Peter Bachrach and Morton Baratz (1969) argued that many issues would be relegated to nondecision-making because leaders only put safe issues on the agenda.

The next logical question is how agenda setting is achieved. Early scholars argued that an item is more likely to get on the agenda as the scope of conflict expands (Schattschneider 1960) and as the groups involved become larger (Cobb and Elder 1972). In John Kingdon’s (1984) model, what gets on the agenda is a function of problem and political streams (the proposal stream presents the alternatives), where policy entrepreneurs play a key role in using their resources to push problems onto the agenda. Frank Baumgartner and Bryan Jones (1993) added to this understanding by claiming that strategic actors not only push items onto the agenda through issue definition (Riker 1986; Stone 1988) but also through the choice of policy venues.

Scholars have investigated the role of various actors in setting the agenda. Researchers have found that in the U.S. government the president is more likely to influence the congressional agenda on foreign policy issues (Peake 2001; Peterson 1994), under conditions of unified control (Taylor 1998), when he makes explicit appeals to the public (Kernell 1986) or when his political capital is high (Light 1982; Mueller 1973). Scholars of the U.S. Congress have shown that the majority party exerts negative and positive agenda control through the powers of the speaker (Cox and McCubbins 1993, 2002; also see Riker 1982). Gregory Caldeira and John Wright (1988) find that amicus curiae briefs influence whether the Supreme Court grants writs of certiorari. The media plays an agenda-setting role by influencing public perceptions about which issues are important (Iyengar and Kinder 1987; McCombs and Shaw 1972; MacKuen 1984), which in turn influences the standards used to evaluate leaders (Miller and Krosnick 2000), and by influencing preferences by framing issues (Druckman 2001; Iyengar 1987). While women and minority groups have had a harder time influencing the agenda, issues of concern to these groups are more likely to make it onto the agenda, given strong group organization, innovative policy proposals, and the presence of minorities and women in elected office (Bratton and Haynie 1999; Epstein, Niemi, and Powell 2005; McClain 1990, 1993; Miller 1990; Thomas 1994).

One of the key consequences of agenda setting is that many issues do not make it onto the agenda. This facet leads to the punctuated equilibrium model of Baumgartner and Jones (1993), where long periods of stability on an issue, are seen, followed by an abrupt shift to a new equilibrium, which can be reached as the issue becomes salient and institutional actors benefit from a new alternative.

AGGREGATE DEMAND

The notion of aggregate demand formally made its appearance in John Maynard Keynes’s (1883–1946) General Theory in 1936 and, in its numerous guises, quickly rose to become a vital concept in economists’ tool
kit of analytical devices. Despite pleas by some economists, notably new classical economists, to reject the aggregate demand/supply framework because of lack of rigorous microeconomic foundations (see, among others, Barro 1994), the aggregate demand function has retained a central but highly debated role in macroeconomic analysis.

Though he regarded it as his major analytical innovation (King 1994, p. 5), Keynes defined his aggregate demand function in a way that would be unfamiliar to most economists nowadays. This is because the aggregate demand function was conceived as a subjective aggregate relation linking entrepreneurs’ offers of employment to the anticipated overall market demand (or expected proceeds) for their firms’ output. Keynes wrote: “Let D be the proceeds which entrepreneurs expect to receive from the employment of N men, the relationship between D and N being written D = f(N), which can be called the aggregate demand function” (Keynes 1936, p. 25). Given entrepreneurial perceptions of firms’ investment plans, and expected flow of household consumption arising from hypothetical employment offers, an aggregate functional relation could be delineated in a two-dimensional D-N space: “The aggregate demand function relates various hypothetical quantities of employment to the proceeds their outputs are expected to yield” (Keynes 1936, p. 55).

There is a positive relationship between aggregate income and employment because increased employment offers will bring forth higher expected proceeds from household consumption. Indeed, the greater the share of spending out of each additional dollar of income—that is, the higher the marginal propensity to consume—the higher the level of additional income associated with increased employment (Asimakopoulos 1991, p. 45).

When depicted in D-N space with an aggregate supply function (the latter resting on a standard Marshallian microfoundation and representing the desired proceeds that would just make it worth the while of entrepreneurs to employ N workers), short-period equilibrium is achieved at the intersection of the aggregate demand and supply curves, dubbed the point of effective demand. On this basis, Keynes rejected classical-type theories founded on the Say’s Law principle (that “supply creates its own demand”) by arguing that the latter doctrine did not assume an independent aggregate demand function that could conceivably result in an equilibrium point at less than full employment.

While the development of his aggregate demand concept was of major theoretical and policy significance, particularly in its support of activist taxation, spending, and monetary policies of aggregate demand management, there were obvious problems with Keynes’s original formulation. For instance, unless the business sector is conceived as one large firm that can envision the impact of its employment decision on its own expected proceeds, how exactly could a multitude of uncoordinated decisions by competitive firms be collectively anticipated by entrepreneurs and represented in an aggregate demand relation? As a result of such theoretical conundrums, the concept was to undergo tremendous transformations during the post–World War II (1939–1945) period as economists sought conceptually less challengeable theoretical constructs.

Even among fundamentalist Keynesians of the early postwar years, such as Sidney Weintraub (1914–1983) and Paul Davidson, the aggregate demand function, D, came to be treated no longer as an expected proceeds curve as perceived by entrepreneurs, but simply as a representation of the intended spending on the part of economic agents (consumers, firms, and governments) associated with hypothetical levels of total employment. Indeed, in the hands of numerous early postwar Keynesians such as Paul Samuelson, Keynes’s original association between sales proceeds and employment was to be transformed into a relation between aggregate intended expenditures of economic agents and the level of real income or output, as depicted in the framework of the popular 45-degree diagrams found in many introductory textbooks (Dutt 2002, p. 329).

Because of its implicit assumption of fixed price, the 45-degree aggregate expenditure relation slowly succumbed to alternative formulations of the aggregate demand function as economists struggled to incorporate the effect of changes in prices within a competing analytical framework. This resulted in redefining a downward-sloping aggregate demand function within aggregate price-output space seemingly comparable to its traditional Marshallian microeconomic counterpart. However, to ensure a negative slope, this latter incarnation of the aggregate demand function had to rely on somewhat more questionable assumptions than its previous upward-sloping Keynesian aggregate expenditure relation in the context of 45-degree diagrams. This is because, as prices rise, it is assumed that the purchasing power of household wealth and cash balances declines and thereby household spending (aggregate demand) also declines. These so-called wealth effects and real balance effects assume that currency held by households plus reserves held by banks exceed the value of bank deposits. In fact, however, bank deposits greatly exceed the value of bank reserves plus currency held by households. Hence, the relevance of real balance effects has been seriously questioned. This is why modern macroeconomic textbooks have slowly been abandoning this form of aggregate demand analysis (in price-output space) and relying simply on a dynamic relation that links inflation to an economy-wide capacity utilization rate—a variant of the Phillips Curve. Unfortunately, the latter is a far cry from Keynes’s unique
formulation of the aggregate demand function that related aggregate expected proceeds to the level of employment.

AGGREGATE DEMAND AND SUPPLY PRICE

Theories of demand and supply have their roots in the works of the English economist Alfred Marshall, who divided all economic forces into those two categories. In 1890 Marshall introduced the concepts of supply price and demand price functions to capture the demand and supply factors facing an individual firm or industry. Marshall’s demand price function relates the quantity of a specific good buyers would be willing to purchase at alternative market prices. The supply price function relates the quantity of goods sellers would be willing to sell at alternative prices. In equilibrium, market price and sales (equal to purchases) would be established at the intersection of these two micro-Marshallian functions.

In his The General Theory of Employment, Interest, and Money (1936), John Maynard Keynes aggregated these Marshallian micro-demand and -supply concepts to achieve an aggregate supply price function and an aggregate demand price function for the macroeconomy. Keynes called the intersection of these aggregate functions the point of effective demand. This “point” indicates the equilibrium level of aggregate employment and output.

AGGREGATE SUPPLY PRICE

Keynes’s aggregate supply price function is derived from ordinary Marshallian microeconomic supply price functions (see Keynes 1936, pp. 44–45). It relates the aggregate number of workers (N) that profit-maximizing entrepreneurs would want to hire for all possible alternative levels of expected aggregate sales proceeds (Z), given the money wage rate (w), technology, the average degree of competition (or monopoly) in the economy, and the degree of integration of firms (cf. Keynes 1936, p. 245). In other words, the aggregate supply price is the profit-maximizing total sales proceeds that entrepreneurs would expect to receive for any given level of employment hiring they reach.

Gross Domestic Product (GDP) is the measure of the gross total output produced by the domestic economy. For any given degree of integration of firms, GDP is directly related to total sales proceeds (Z). If all firms are fully integrated—that is, if each firm produces everything internally, from the raw materials to the final finished product—then aggregate sales proceeds (Z) equals GDP. If all firms in the economy are not fully integrated, then Z will be some multiple of GDP depending on the average degree of integration of all firms.

Keynes argued (1936, p. 41) that money values and quantities of employment are the only two homogeneous “fundamental units of quantity” that can be added together to provide meaningful aggregates. Accordingly, the aggregate supply price (expected sales proceeds) associated with alternative levels of employment should be specified either in (1) money terms (Z) or (2) Keynes’s wage unit terms (Z_w), where the aggregate money sales proceeds is divided by the money wage rate (w). Hence the aggregate supply function is specified as either:

\[ Z = f_1(N) \]  

or

\[ z_w = Z/w = (f_1(N)/w) = f_2(N) \]

The Marshallian supply curve for a single firm (s_f) relates the profit-maximizing output possibilities for alternative expected market prices. This supply price function (s_f) of any profit-maximizing firm depends on the degree of competition (or monopoly) of the firm (k_f) and its marginal costs (MC_f). In the simplest case, in which labor is the only variable factor of production, \( MC_f = w/MPL_f \) where w is the wage rate and MPL is the marginal product of labor. Accordingly, the Marshallian microeconomic supply price function is specified as

\[ s_f = f_3(k_f, MC_f) = f_3(k_f, (w/MPL_f)) \]

Lerner’s (1935) measure of the degree of monopoly (k_f) is equal to (1 – 1/E_{g/f}) where E_{g/f} is the absolute value

BIBLIOGRAPHY

Mario Seccareccia
of the price elasticity of demand facing the firm for any given level of effective demand. For a perfectly competitive firm, \( k_f = 0 \) and only marginal costs affect the position and shape of the firm’s supply price function.

The Marshallian industry supply price function (\( s \)) is obtained by the usual lateral summation of the individual firm’s supply curves

\[
s = f_4(k, MC) = f_4(k, (w/MPL))
\]

where the symbols without subscripts are the industry’s equivalent to the aforementioned firm’s variables.

Although output across firms in the same industry may be homogeneous and therefore capable of being aggregated to obtain the industry supply quantities (as in equation 4), an assumption of output homogeneity cannot be accepted as the basis for summing across industries to obtain the aggregate supply price function of total output (Keynes 1936, ch. 4). Because every point on the Marshallian industry supply function (\( s \)) is associated with a unique profit-maximizing combination of price (\( p \)) and quantity (\( q \)), the multiple of which equals total industry expected sales proceeds (\( z \)) (i.e., \( pxq = z \)), and because every industry output level (\( q \)) can be associated with a unique industry hiring level \( n \) (i.e., \( q = f(n) \)), then every point of equation 4 of the \( s \)-curve in \( p \) vs. \( q \) quadrant space can be transformed to a point on a \( z \)-curve in \( z \) vs. \( n \) quadrant space to obtain

\[
z = f_5(n).
\]

These equation 5 industry-supply functions are aggregated across all industries to obtain Keynes’s aggregate supply price function in terms of aggregate money proceeds (\( z \)) and the aggregate quantity of employment units (\( N \)) as specified in equation 1. To achieve unique aggregation values of \( z \) for each possible \( N \), Keynes assumed that corresponding to any given point of aggregate supply price there is a unique distribution of income and employment between the different industries in the economy (Keynes 1936, p. 282).

Though Keynes describes the aggregate supply price function and its inverse, the employment function, in The General Theory, he unquestioningly accepted Marshall’s microeconomic supply price concept as the basis for the aggregation he used to aggregate supply price function. Consequently, the bulk of The General Theory is devoted to developing the characteristics of aggregate demand price function, for it was the latter that Keynes thought was his revolutionary and novel contribution.

AGGREGATE DEMAND PRICE

Keynes’s “Principle of Effective Demand” (1936, ch. 2) attacked classical theory’s fundamental building block, known as Say’s Law. This law presumes that “supply (equal to total output produced and income earned) creates its own demand.” Under Say’s Law all income, whether spent on consumption or saved, is presumed to be spent on the products of industry. Accordingly, the total costs of aggregate production incurred by firms (by definition equal to aggregate income earned) at any level of employment is presumed to be entirely recouped by the sale of output at every possible level of employment and output. The factors determining the aggregate demand price for products are presumed to be identical to those that determine aggregate output (aggregate supply price) for every possible given level of output.

Keynes justified his position by declaring that Say’s Law “is not the true law relating the aggregate demand price function and the aggregate supply price function.… [Such a law] remains to be written and without … [it] all discussions concerning the volume of aggregate employment are futile” (1936, p. 26). Keynes’s General Theory developed the characteristics and properties of the aggregate demand price function to explain why it was not identical with the aggregate supply function—that is, why supply does not create its own demand.

Keynes’s aggregate demand price function related the expected aggregate planned expenditures of all buyers for all possible alternative levels of aggregate income and employment. An expanded taxonomy for the components of the aggregate demand price relationship was necessary to differentiate Keynes’s analysis from the aggregate demand price function implicit in the classical Say’s Law. Under Say’s Law, all demand for producibles is collected in a single category (\( D_1 \)) that is solely a function of (and is equal to) income earned (supply) at all possible alternative levels of employment. Keynes split aggregate demand price into two categories, \( D_1 \) and \( D_2 \), where \( D_1 \) represents all expenditures that “depend on the level of aggregate income and, therefore, on the level of employment \( N \),” and \( D_2 \) represents all expenditures not related to income and employment (1936, pp. 29–30). These two categories make up an exhaustive list of all possible classes of demand.

Unlike the Say’s Law \( D_1 \) category, Keynes’s \( D_1 \) spending does not necessarily equal aggregate income, because some income might be saved—and in Keynes’s analysis, savings out of current income is never immediately used for the purchase of producibles. Keynes identified \( D_1 \) as the propensity to consume (i.e., consumption expenditures) using current income. Keynes argued that some portion of current income was not spent on consumption, but was instead saved in the form of money or other liquid assets to permit the saver to transfer purchasing power to the indefinite future. Moreover, an essential property of money (and all liquid assets) is that it is not producible in the private sector by the employment of labor (Keynes 1936, ch. 2).
Thus, the decision to save a portion of income as money or other liquid assets involves “a non-
employment inducing demand” (cf. Hahn 1977, p. 39) that is incompatible with Say’s Law.

Because all income received goes either to planned consumption or planned savings; if Keynes’s second expend-
diture category, $D_2$, were to be equal to the planned savings at every possible alternative level of employment, then Say’s Law would be reinstalled. To demonstrate why $D_2$ is not equal to a planned savings function, Keynes assumed the existence of an uncertain future (i.e., a system in which the classic ergodic axiom is not applicable). By uncertain Keynes meant that the future can neither be known in advance nor reliably statistically predicted through an analysis of existing market price signals. Given an uncertain (nonergodic) future economy, future profits, the basis for current $D_2$ investment spending, can neither be reliably forecasted from existing market information, nor endoge-
nously determined via planned savings. Instead, the expected profitability of investment spending ($D_2$) depends on the optimism or pessimism of entrepreneurs—what Keynes called “animal spirits.” In such a world, neither in the short run nor the long run can $D_2$ expenditures be a function of current income and employment.

Keynes’s general theory, therefore, implies that the aggregate demand price function is not identical with the aggregate supply function at every possible alternative level of employment. Thus, the possibility exists for a unique single intersection (the point of effective demand) at less than full employment.

**AGGREGATE SUPPLY**

Aggregate supply is an aggregate analogue of the concept of supply for individual goods and services markets that is used in microeconomic analysis. The aggregate supply of goods and services is usually taken to be related to the aggregate price level, a relationship that is called the aggregate supply function. The curve representing this relation is called the aggregate supply curve, and is a component of the popular aggregate demand–aggregate supply analysis of short-run macroeconomics, which abstracts from longer run issues such as capital accumulation and tech-
nological change.

The economist John Maynard Keynes defined the aggregate supply function as the relation between the level of employment and the aggregate supply price, which is the expectation of proceeds that makes it just worthwhile for firms to offer that level of employment, and distinguished it from the aggregate demand function that shows the relation between the proceeds that firms expect to receive and the level of employment. The modern use of aggregate supply and demand remains close to Keynes’s usage but replaces the relation between the value of output (or total proceeds) and employment to that between the price level and the quantity of output. Early econom-
ics textbooks after Keynes took the aggregate supply (AS) curve to be positively sloped like its microeconomic counterpart, but as shown in Figure 1, assumed it to be rela-
tively flat at low levels of output, having an upward slope at intermediate levels, and to become increasingly steeper as the economy approaches full employment. At low lev-
els of output many resources, including labor, are unuti-
lized, and increases in output can be obtained without increases in input prices and without experiencing significant diminishing returns, so that firms are willing to pro-
duce more without any increase in the price. As output expands, diminishing returns sets in and input prices begin to rise, so that firms require a higher price to pro-
duce more. Finally, when full employment of labor is reached with the corresponding output level shown by $Y_f$ in Figure 1, no further expansion in output is possible.

In subsequent (late twentieth-century) presentations this representation has been replaced by a variety of oth-
ers, the relevance of which depend on the precise assump-
tions made about the economy and the time horizon one has in mind. The most popular representation, common to a number of Keynesian and monetarist approaches, takes the short-run aggregate supply curve to be positively sloped, as shown by the curve AS in Figure 2, and the long-run aggregate supply curve as vertical as shown by the vertical line at $Y_n$ (denoting the natural level of employment, which is consistent with wage-price stabili-
ity) in the figure. The short-run curve can extend beyond the long-run curve as shown in the figure, implying that

Paul Davidson

INTERNATIONAL ENCYCLOPEDIA OF THE SOCIAL SCIENCES, 2ND EDITION
the economy can in fact produce beyond the level shown by the longer-run curve, for instance by hiring more workers than normal by paying overtime wages.

There are several interpretations of this configuration. One interpretation—common among the neoclassical synthesis Keynesians—assumes that firms operate in a perfectly competitive market and with diminishing returns to labor. With the money wage given in the short run, a higher price makes profit-maximizing firms increase employment and production. With the money wage flexible in the longer run, the money wage changes; if there is unemployment, the money wage falls, so that the aggregate supply curve shifts down. In the long run the economy is at full employment, where the demand for labor and the supply of labor (both of which depend on the real wage) are equal, so that the economy is at $Y^*_n$ in the figure. A second interpretation—made by the early monetarists—takes the price level expected by workers to be given, but allows the money wage to adjust to clear the labor market, in the short run. A higher price increases the money wage as firms increase their demand for workers, and workers supply more labor because with the fixed expected price their expected real wage is higher. Over the longer run the expected price adapts to the actual price, which shifts the AS curve; in long run equilibrium price expectations are fulfilled and the economy is at $Y^*_n$. A similar interpretation—often made by new Keynesians—assumes that the money wage depends on the expected price and on labor market conditions reflected by the unemployment rate, and that the price level is determined by firms as a markup on unit labor costs. In the short run, with expected price given, a higher level of output implies a lower unemployment rate, a higher money wage and a higher price. In the longer run, as expected price adapts to the actual price, the AS curve moves; for instance, if the economy produces below $Y^*_n$, the expected price falls, so that the AS curve shifts down. The long-run supply curve is given at the natural rate of unemployment at which the wage and price are stable, as determined by labor market conditions and the pricing policies of firms. Unemployment may prevail due to, for instance, firms keeping wages higher than the market, clearing one to make workers exert more effort, thereby becoming more productive.

In all of these interpretations, in the short run the economy is on the AS curve, at a position determined by the AS curve and the downward-sloping aggregate demand (AD) curve. Since the short-run position of the economy is not at $Y^*_n$, the price and wage will change; at the intersection shown in Figure 2, the price and wage falls so that AS shifts down, and the economy moves along the AD curve until long-run equilibrium is attained at $Y^*_n$, so that the vertical line can be given the interpretation of the long-run AS curve. This adjustment occurs because (as is shown by the negative slope of the AD curve) a reduction in the price reduces the demand for money (since less money is required to make transactions), which makes asset holders want to lend more

---

**Figure 1**

**Figure 2**
thereby reducing the interest rate and inducing more spending. The nature of the short-run and long-run aggregate supply curves, given by AS and $Y_n$, implies that changes in the aggregate demand curve (such as fiscal and monetary policy shifts, or changes in expectations which affect investment) have an effect on output in the short run, but not in the long run.

This interpretation, however, is not accepted by all approaches. Some take the view that the economy is always on the vertical curve, so that it is the only AS curve for the economy. These views, which are associated with the new classical approach, assume that the money wage is perfectly flexible (in contrast to the neoclassical Keynesians) and that economic agents have rational expectations (in contrast to the early monetarists) and do not make systematic forecasting errors, so that it is inappropriate to take the expected price as given in the short run. In this approach, the AS curve is the vertical curve at full employment, so that aggregate demand shifts do not affect the level of output. However, this result need not hold if there are wealth effects on labor supply. With the traditional interpretation based on the supply and demand for labor and market clearing wage, a change in the price level can affect the value of real wealth, which in turn can affect the supply of labor and the level of employment.

Approaches having the rising short-run AS curve need not accept the interpretation that vertical curve is the long-run AS curve. First, the economy may not converge to $Y_n$, so that the vertical line cannot be given the interpretation of the long-run supply curve. For instance, if the economy is below $Y_n$ in the short run, the downward shift in the AS curve need not take the economy to $Y_n$ if the AD curve also shifts to the left or because it is not negatively sloped if, for instance, as the money wage falls aggregate demand falls as wage income falls (with a higher propensity to spend out of wage than out of profit income) or because firms reduce investment when the price falls. Second, even if the economy converges toward $Y_n$, its level may change endogenously, so that the long-run supply curve need not be vertical. For instance, according to some new Keynesian contributions, a fall in output and employment below the natural rate can make outsiders in the labor market lose their ability to reduce the wage, which increases the natural rate of unemployment and reduce $Y_n$. In these cases the aggregate supply side of the story implies that the aggregate demand side can have effects not only in the short run, but also in the longer run.

---

**AGGRESSION**

Aggression is defined as behavior that is intended to harm others and that is perceived as harmful by the victim. Because aggression is such a broad phenomenon, subtypes of aggression have been proposed to reconcile discrepant research findings—for example, that not all aggression is angry. Subtypes of aggression abound, but two classifications are most important: reactive versus proactive aggression, and physical versus social aggression.

**Reactive aggression** is angry, impulsive, and typically occurs in response to provocation, whereas **proactive aggression** (sometimes called instrumental aggression) is more cool and deliberate and is deployed to achieve a social goal. Although reactive and proactive aggression are highly correlated, they seem to be related to different correlates and developmental outcomes (Coie and Dodge 1998). Reactive aggression is related to overattributing hostility in social interactions, whereas proactive aggression is related to expecting that physical aggression will have positive outcomes. Reactive aggression is associated with parental abuse, behavior problems in the classroom, and peer rejection and victimization. Proactive aggression is related to friendship similarity and leadership, and also predicts future antisocial behavior.

Because hurtful behavior can take nonphysical forms, perhaps especially for girls, other important subtypes to consider are physical and social aggression. **Social aggression** is behavior that hurts others by harming their social status or friendships. This form of aggression includes malicious gossip, friendship manipulation, and verbal and nonverbal forms of social exclusion (Underwood 2003). Social aggression is sometimes called indirect or relational aggression, but the construct of social aggression acknowledges that harm to relationships can be both direct and indirect, and that social exclusion can be both verbal and nonverbal. Here again, children’s propensities to engage in social and physical aggression are highly correlated. Both social and physical aggression may take reactive or proactive forms.

---

**BIBLIOGRAPHY**

---

*Amitava Krishna Dutt*
Across almost all cultures that have been studied, boys and men are more physically aggressive than girls and women are. However, evidence for gender differences is much less clear for social aggression. Because base rates for girls’ physical aggression are so low, without a doubt girls are more socially aggressive than they are physically aggressive. However, this does not necessarily mean that girls are more socially aggressive than boys are, and research findings conflict. Future research should examine whether social aggression unfolds differently in girls’ groups than in boys’ groups.

**DEVELOPMENTAL ORIGINS AND OUTCOMES OF PHYSICAL AGGRESSION**

Physical aggression emerges in the first two years of life (Tremblay et al. 2005) and may have biological correlates. Experts disagree as to whether there is a strong genetic component for physical aggression, but genes likely underlie temperamental qualities that have been shown to be related to aggression in childhood, which appears in such forms as impulsivity, negative emotionality, and reactivity. Although testosterone has long been thought to be related to physical aggression, the relation between this hormone and physical fighting is complex and at best indirect. Elevations in testosterone are more related to social ascendance than aggression specifically.

Socialization experiences may relate to a child’s propensity for physical aggression. Children who experience harsh, abusive parenting may develop a bias toward interpreting ambiguous social cues as hostile, which leads them to be sensitive to slights and prone to reactive aggression. Children whose parents have an authoritarian style (punitive and low on warmth) may be more likely to have behavior and peer problems. Children who engage in coercive cycles with parents, in which the child’s behavior escalates until the parent gives in, thereby reinforcing the highly noncompliant behavior, are more prone to a number of antisocial behaviors that may include physical aggression. Children may also become increasingly aggressive as a result of exposure to media violence on television or in video games, although the direction of causation is difficult to disentangle because physically aggressive children may be more drawn to violent media content.

Physical aggression is associated with a number of adjustment problems, in childhood and beyond. Children who fight are at risk for peer rejection and academic difficulties; as adolescents, they are at risk for dropping out of school, delinquency, and substance use. Although fewer girls than boys fight physically, those that do are just as much at risk for these negative outcomes (Putallaz and Bierman 2004). For girls, physical aggression in childhood is associated with adolescent childbearing, and these adolescent mothers who were aggressive as children are at heightened risk for having children with health and behavioral problems.

**DEVELOPMENTAL ORIGINS AND OUTCOMES OF SOCIAL AGGRESSION**

Although much less is known about the developmental origins of social aggression, interesting hypotheses are emerging. Children may learn the power of social aggression by watching their parents resolve marital conflicts in ways that involve triangulating others and threatening relationship harm, or by watching how parents refrain from open conflict with friends but instead malign others behind their backs. Children may also learn social aggression by observing peers or siblings, or perhaps even by seeing relationship manipulation and malicious gossip gleefully depicted in television and movies, not only those aimed at children and adolescents but also adult programming.

Engaging in high levels of social aggression and chronically being victimized are both associated with psychological maladjustment for children. Children, especially girls, who are frequently victimized report elevated levels of depression, loneliness, anxiety, and low self-concept. In addition, children who frequently perpetrate social aggression are disliked by peers, and they report feeling lonely and anxious. In young adult women, being nominated by peers as high on social aggression has been shown to be related to bulimia and borderline personality disorder. As suggested by Nicki Crick and Carolyn Zahn-Waxler (2003), high levels of social aggression may be associated with the psychological problems to which girls and women are most vulnerable.

**FUTURE RESEARCH**

Future research should examine how physical and social aggression are related and unfold together in both real and developmental time. Promising strategies to reduce physical aggression involve training parents to respond strategically to their children by rewarding positive behavior and not reinforcing aggression, and teaching children skills that will help them regulate emotions and form relationships. Some of these same strategies may be helpful for reducing social aggression, and adding components that address social aggression may enhance the effectiveness of violence prevention programs.

AGNOSTICISM
Agnosticism concerns the withholding of a person's judgment, or belief, on a matter. Such withholding entails neither believing in favor of nor believing against a phenomenon in question. With regard to the question of God's existence, for instance, an agnostic would believe neither that God exists nor that God does not exist. Agnosticism can be directed toward any alleged phenomenon. It need not be limited to the issue of God's existence. It thus is equivalent to skepticism. One might be agnostic about the external world, minds, God, non-physical entities, causal relations, and future truths, among other things. Sextus Empiricus (fl. c. 150 CE), David Hume (1711–1776), and Bertrand Russell (1872–1970) have supported influential versions of agnosticism.

Cognitive agnosticism about an alleged entity (say, God) entails that, owing to counterbalanced or at least highly mixed evidence, one should withhold belief regarding the proposition that God exists. That is, one should neither believe that God exists nor believe that God does not exist. Doxastic agnosticism about God, in contrast, entails that one actually withholds belief regarding the proposition that God exists. A doxastic agnostic can consistently say: I withhold judgment whether God exists, but I have no commitment regarding the status of the overall available evidence on the matter. So a person could be a doxastic agnostic without being a cognitive agnostic. Cognitive agnostics about God, however, are logically required to recommend doxastic agnosticism about God, at least on cognitive grounds, even if they fail at times actually to withhold judgment regarding God's existence.

A common motivation for agnosticism regarding an issue is a concern to avoid error or at least to minimize the risk of error in one's beliefs. The concern is that if relevant evidence is highly mixed, then in answering either yes or no to a question, one seriously risks falling into error, that is, false belief. The better alternative, according to agnostics, is to refrain from answering either yes or no, that is, to withhold judgment. Refraining from believing that something exists while refraining from believing that it does not exist can save one from mistaken belief. There is, however, a price to pay: One will then miss out on an opportunity to acquire truth in the area in question. For instance, it is true either that God exists or that God does not exist. Agnostics in principle forgo acquiring a truth in this area of reality.

Agnostics about the issue of God's existence do not endorse atheism about God. They do not affirm that God does not exist; nor do they propose that our overall available evidence indicates that God does not exist. Agnostics hold that (at least for their own situation) atheism goes too far in the negative direction, just as (they hold for at least their own situation) theism goes too far in the positive direction. Theism, like agnosticism and atheism, can be either cognitive or doxastic. Doxastic theists hold that God exists. Cognitive theists hold that, owing to the overall available evidence, one should believe that God exists. Agnostics hold that, at least for their own situation, theism and atheism go too far, positively or negatively, in the area of belief.

An underlying assumption of cognitive agnosticism is that God's existence would need to be more obvious to justify acknowledgment. This assumption has given rise to extensive contemporary discussion about divine hiddenness and elusiveness. The discussion shows no sign of ending any time soon.

AGRIBUSINESS

Agribusiness is related to the production of food and fiber. Agribusiness includes agricultural input industries, commodity processing, food manufacturing and food distribution industries, and third-party firms that facilitate agribusiness operations including bankers, brokers, advertising agencies, and market information firms. Harvard Business School professor Ray A. Goldberg introduced the term *agribusiness* together with coauthor John H. Davis in 1955 in a book titled *A Concept of Agribusiness*. Food and fiber products that rely upon agricultural production, which is inherently decentralized and subject to the vagaries of weather and disease, often are perishable and require specialized economic institutions and public policies including sanitary regulations. Decentralized farmers of a particular commodity, such as milk, have organized agricultural marketing cooperatives to aggregate their product and coordinate sale to large food-manufacturing firms in a fashion that enhances product quality, economic efficiency, and fairness of the market pricing system.

Similarly, on the input side there are tightly coordinated (contract farming) arrangements for chicken and pork. In the beef and grain industries, agribusiness coordination uses complex pricing mechanisms, such as futures markets, to hedge risk and price products. Closer to the consumer, large supermarket chains have integrated back into the wholesaling of food products and developed private-label food products (such as bread with the supermarket’s name on it) to countervail the power of branded food-product manufacturers who would charge a premium for their products.

Public policies toward the agribusiness sector have been critical in creating the food and fiber system that is seen throughout the world. Food safety and health regulations are critical. Agricultural commodity and pricing policies in developed countries aid in the pricing of commodities such as milk, wheat, corn, soybeans, cotton, and other products. These policies attempt to stabilize commodity price cycles and to ensure the economic health of the agricultural industries.

Public policy also aids in the organization of agricultural marketing and input supply cooperatives and the development of commodity promotion programs wherein farmers fund advertising efforts such as the “Got Milk?” program in the United States. Here the desire is to improve the incomes of farmers by enhancing their bargaining power and expanding the demand for their products.

Antitrust and competition policy also affects agribusiness. Over time the food systems in the United States and other countries have become industrialized. Relatively few large food processing firms and relatively few large retailing organizations sit between decentralized agricultural production and the general consuming public. Antitrust/competition policy examines proposed mergers and acquisitions in these concentrated industries to determine whether they would increase pricing power to the disadvantage of consumers or farmers. Those policies also prohibit price-fixing cartels and attempts to monopolize industries.

In the March-April 2000 issue of the *Harvard Business Review*, Goldberg revisited the concept of agribusiness with Juan Enriquez. He observed that ethanol, an additive to gasoline, and pharmaceutical products were made from agricultural outputs. Agribusiness in the 2000s also includes forestry and forest products and the plant nursery industry.

AGRICULTURAL ECONOMICS

The field of agricultural economics deals with resource allocation and utilization and income distribution and growth in land-intensive activities. Traditionally such activities were confined to crops and livestock production, which, accordingly, have been the accepted domain of agricultural economics. As the relative economic importance of agriculture declines (steeply in the case of the industrialized nations) and as natural resource depletion and degradation loom large, agricultural economics has come to be seen as inseparable from the economics of renewable resources and the environment.

Established areas of study in agricultural economics include farm-level decision making, production economics and resource use efficiency, household economics and consumer behavior, agricultural markets and market outcomes, food safety and variety, international trade in agricultural commodities, and nutrition. The contemporary
field includes natural resource and environmental economics, agribusiness, forestry economics, and aspects of health economics, community and rural development, food security, and economic development (see, for example, Cramer, Jensen, and Southgate, 2001).

The affinity between traditional agricultural economics and environmental and resource economics is more than a matter of their common concerns with land, water, and other natural resources; it is also rooted in shared principles and methods of research. This accounts for the reincarnation of most academic departments of agricultural economics as departments of agricultural and resource economics since the early 1980s.

Agricultural economics is a branch of neoclassicism, the reigning paradigm in economics. Its origins are coterminal with the ascendancy of neoclassicism from the 1870s on. Indeed, agricultural economics has provided its parent with the archetype of the neoclassical textbook ideal: firms without market power (farms), workers without bosses (peasant families), and products without private identities (cereal commodities). This model remains the hobbyhorse not just of agricultural economists but of economists generally; ironically, though, agricultural markets have long ceased to be guided by the invisible hand, given ubiquitous state interventionism. Nonagricultural markets ruled by competition, on the other hand, have long been exceptions, not the rule.

Apart from supplying a deceptively persuasive model bolstering neoclassical preconceptions, the theoretical significance of agricultural economics consists in its unswerving adherence to these preconceptions. Agricultural economics has always been highly micro-oriented in both theoretical and empirical analyses, relying on the standard models of rational decision making by households (as both consumers and producers) and of profit-maximizing farms (see Norton 2004).

Claiming universal validity for this paradigm, Nobel prize winner Theodore Schultz famously described developing nations’ agriculture-dominated economies as “poor but efficient,” a narrowly technical-economic conclusion that seemed incongruous with endemic resource underutilization, including underemployment, egregious social structures of exploitation, and momentous instances of agrarian conflict and revolution (Rao 1986).

If agricultural economics deals with the narrowly technical issues of resource allocation and utilization that arise in our relation to nature and its cultivation, agrarian economics may be taken to deal with broader issues of social structure and regulation that arise in our relation to each other as we relate to nature. Advancing socially relevant knowledge in these twin fields is vital to our future. But this will depend on conscious efforts to integrate the twin fields rather than, as agricultural economics has done, ignoring the social dimension by hypostatizing itself.

**AGRICULTURAL INDUSTRY**

The emergence of agriculture was one of the most prominent events in human history, and transformations in agriculture have proved to be among the most significant sources of social change. Even in the postindustrial world, agriculture and agricultural change continue to have major implications for human societies. Fundamentally, humans remain absolutely dependent on agriculture for food and many other products used on a daily basis.

The emergence of and subsequent developments in agriculture have transformed human societies in at least three major ways: First, when compared to hunting and gathering, agriculture greatly increased the amount of food that could be produced and made food production much more consistent and dependable. With an ever-increasing and more dependable food supply, the human population that the earth can support has increased dramatically (Vasey 1992). Second, agriculture made permanent settlement possible because it was no longer
necessary for humans to follow herds of animals or go out in search of edible plants. Third, as agriculturally based societies developed, the ownership or control of agricultural lands became perhaps the most important source of wealth and power. Extensive inequality quickly followed.

Agricultural production has always been, and continues to be, totally dependent on two broad sets of input. These include: (1) the force, energy, or labor to accomplish necessary agricultural tasks such as preparing the soil, planting seeds, removing weeds, and harvesting; and (2) environmental resources such as soil, water, and sunshine (Schlebecker 1975). From the beginning, attempts to procure these resources have had substantial societal impacts.

For most of agriculture’s long history, human beings, with assistance from domesticated animals, have provided the bulk of agricultural labor. Agriculture has always faced the unique and somewhat troublesome challenge of securing an adequate labor supply: While an industrial labor force can generally be used consistently and efficiently throughout the year, the same is not true in agriculture, where the production of most commodities is seasonal. Consequently, throughout the year there are periods of extensive labor needs, primarily during planting and the harvest, followed by periods when labor requirements are minimal as biological processes unfold (Mann and Dickinson 1978). Employing an agricultural workforce large enough to meet labor requirements during peak seasons means that during most of the year this labor force will be underutilized, while the cost of feeding and housing workers remains constant. On the other hand, if a year-round workforce is not retained and attempts to secure a sufficient temporary labor force during critical labor-intensive periods fail, the results could be disastrous.

Throughout history, attempts to deal with the unique labor problems of agriculture have taken a variety of courses. Initially, approaches revolved around securing an adequate but relatively cheap human labor supply. More recently, technological solutions were sought in which machines were developed to replace human labor in the production process. Both paths have had major social consequences.

**MAINTAINING AN ADEQUATE LABOR FORCE**

Historically, agricultural lands have often been unequally distributed, largely controlled by wealthy and powerful landowners who sought for ways to maintain a sufficient agricultural labor force at relatively low costs. Some of the solutions have resulted in some of the darkest chapters of human history. In the past couple of centuries more equitable labor solutions have been attempted.

**Feudalism** During the Middle Ages in Europe, and at times in Japan, China, and other areas, feudalism emerged as a complex and varied cultural system that provided a way for the wealthy and powerful aristocracy to maintain a constant and relatively inexpensive agricultural labor force. In theory, feudalism resembled a pyramid. At the top of the pyramid was the monarch—a king, emperor, or shogun—who owned all of the land within the kingdom. Since it was impossible for the monarch to supervise or control such a large area, he or she divided the land and granted control of various segments to upper-class nobles. These nobles were the second level on the pyramid. In exchange for the land grant, the noble would swear an oath of loyalty to the monarch, collect taxes from the land to be shared with the monarch, and provide soldiers when requested. Often upper-level nobles would further subdivide the land under their control and provide land grants to lower-level nobles, who in turn, were expected to collect taxes to be shared with those above them and to provide soldiers. Further subdivisions were found in some areas. If production increased, greater levels of wealth would flow to all levels up the pyramid. The higher up the pyramid an individual resided, the greater the power, prestige, and financial benefits.

At the base of the pyramid were the peasantry and serfs, who often comprised up to 95 percent of the population. These individuals provided a constant and cheap source of agricultural labor, became soldiers when requested, and generally lived near abject poverty. They owned virtually nothing, spent their days working as day laborers on the lands of the aristocracy, and had few freedoms. The entire feudal system was based on ascribed status, where a person’s position in life was almost entirely a function of his or her birth.

**Slavery** Slavery has a long and painful chapter in world history. While slaves have been used in a variety of economic endeavors, slavery has most prominently been a way of maintaining a consistent and cheap agricultural labor force. Although slavery has been a part of numerous cultures throughout the world, perhaps the most vivid example of slave labor in agriculture involved exporting Africans to the Americas to work as agricultural slaves. Studies by David B. Davis estimate that between 1500 and 1870, about 9.4 million Africans were transported to the Americas. About 48 percent of the slaves arrived in the Caribbean Islands, 41 percent were sent to Brazil, about 6 percent arrived in the southern United States, and the remaining 5 percent were sent to mainland Central and South America (Davis 2006).

Slavery was a part of an extremely productive agricultural system that generated great wealth to those who owned land and slaves and allowed most slaveholders to
live a life of relative comfort. However, this wealth was generated by the labor of slaves who endured torture, degradation, and were treated as property. Individuals were often separated from friends and family and sold like animals. One of the lasting consequences of slavery is a legacy of racism. To justify the race-based slavery that existed in the Americas, an ideology emerged in which the slave-owning race was defined as superior while the enslaved race was defined as inferior. The ramifications of this ideology continue to have implications for human interactions in modern society.

The Family Farm When the United States became an independent nation, policies were instigated that were intended to create an agricultural system based on numerous medium-sized family farms. The traditional agricultural labor problems would be solved by having the farmer and other family members provide the vast majority of the labor. Family labor was relatively effective because family members could be used extensively when labor needs were high and idled with minimal costs when not needed (Buttel et al. 1990). A nation of family farmers would also largely eliminate the tremendous inequality inherent in a system of landed aristocracy. The Homestead Act of 1862 perhaps best exemplifies the policy of encouraging family farms in the United States. This act made it possible for a settler, after paying a small registration fee and residing on and working 160 acres of land for five years, to gain clear title to that land. The opportunity to own one's own land was the magnet that drew millions of immigrants from Europe to the United States. In time, millions of medium-sized, full-time family farming operations dominated agriculture in the United States.

Collective Agriculture Karl Marx expressed great concern over the inequality inherent in the feudally based agricultural system that prevailed in Europe. He felt the basic problem was that a few individuals owned the land while the masses provided the agricultural labor. Following the Bolshevik Revolution of 1917, the existing agricultural system was totally overturned in areas under communist control. In time a system of large state-owned, centrally controlled collective farms was developed. The manifest goal of collective agriculture was equality. All members of the collective farm worked together and shared equally in the output. Despite an egalitarian land-ownership system and production units that were conducive to machinery and other modern technology, the productivity of collective farms was never as extensive or as efficient as communist leaders hoped it would be.

THE MECHANIZATION OF AGRICULTURE

Prior to about 1800, the vast majority of the world's population lived on farms in rural areas in an economy based on subsistence agriculture. It was necessary for nearly everyone to be involved in agriculture because most farms were barely able to produce what was needed by their own workers, and thus there was little surplus. Then in the mid-eighteenth century, the Industrial Revolution emerged in Great Britain. Developments in science, technology, and machinery greatly increased the efficiency of human labor. Initially, the industry most extensively affected was agriculture. By using increasingly advanced machines, farmers were able to produce an ever-greater surplus of food and fiber. With fewer workers needed in agriculture, a labor force was available to work on the new machines coming into use in manufacturing and industry.

For many farmers, the development of machines was a welcome solution to agricultural labor problems. Machines had several advantages over human labor. Once a machine was purchased, it could be stored during periods of disuse for little additional cost and made quickly available when needed. Additionally, machines eliminated much of the back-breaking work once associated with farming.

Despite some nineteenth-century breakthroughs, a large proportion of the world's population remained directly involved in agricultural production into the early decades of the twentieth century. Between about 1940 and 1970 the mechanization of agriculture proceeded rapidly in economically advanced nations. The impact of this process was dramatic. The mechanization of agriculture changed the very nature of farm work, totally transformed the face of rural areas, and had dramatic implications for urban and nonfarm populations as well. By utilizing new technologies, the labor capacity of farmers was greatly increased, which enabled them to operate progressively larger farms. With a rapid increase in farm size, there was a corresponding decline in the number of farms (Albrecht and Murdock 1990). In the United States, Calvin Beale (1993) described the subsequent transition as the largest peacetime movement of people in history as millions of people left the farm and moved to urban areas seeking industrial employment. The industrialization of agriculture also significantly altered what was once a family-farm-based agricultural structure. Increasingly, agriculture in the United States and other advanced economies became more dualistic: Most production now comes from a number of large and highly mechanized farms, with another large segment of the farm population running small part-time retirement or hobby farms. The number of medium-sized family farms has declined substantially.
The extent to which agriculture has been transformed by industrialization varies greatly from one part of the world to another. In economically advanced nations, a highly mechanized agricultural sector is extremely productive and typically less than 5 percent of the labor force is involved in agriculture. The large nonfarm sector is then able to produce goods and services that add to the quality of life in these countries. By contrast, in less developed countries a majority of the labor force remains involved in agricultural production and the standard of living is much lower.

**AGRICULTURAL ENVIRONMENT AND SOCIETY**

Agricultural production has always been and continues to be closely tied to the natural environment (Albrecht and Murdock 2002). The quality and quantity of resources available play a major role in determining which commodities can be produced and in what quantity. While innumerable environmental factors influence agricultural production, a few are obviously vital. Successful agricultural production requires the appropriate combination of soil, water, and temperature. If these factors are missing or vary too widely, production will either not occur or will be somewhat limited. Although the production of agricultural commodities requires all of these essential resources, the amounts required vary substantially from one commodity to another. Wheat can be produced in areas that experience harsh winters and have relatively short growing seasons, while citrus fruits cannot, and rice production requires substantially more water than cotton production. Thus, basic environmental differences severely limit farm production in some areas, and certain commodities cannot be effectively produced in other areas.

Throughout history, humans have attempted to overcome the shortcomings of their agricultural environment. Unwanted vegetation is removed, complex irrigation systems carry water to land whose natural rainfall is insufficient, and fertilizers, including animal manure, are added to the soil to improve its natural fertility. As a continuation of these efforts, scientists are seeking to overcome environmental limitations through developments in biotechnology. The implications are extensive. On the one hand, agricultural production far exceeds what it would be otherwise. On the other hand, some environmental resources have been severely depleted and other significant environmental pollution problems have emerged.

In many cases, agricultural production has severely impaired the environment. Soil erosion is a classic example. Many great civilizations of the past were founded on an extensive base of fertile soil. Ample soil allowed for surplus farm production, which freed part of the population from agriculture and permitted some workers to become artisans, engineers, and artists (Dale and Carter 1955; Lowdermilk 1953). However, with few exceptions, humans have not been able to sustain a progressive civilization in one locality for more than a few hundred years. Over time the natural resource base (particularly the soil base) that permits surplus production becomes depleted. As resources are depleted, surplus production decreases and the civilization declines (Brown 1981). Lowdermilk (1953), for example, found evidence of over a hundred dead villages in Syria. These villages now stand on bare rocks with the soils completely washed or blown away. He concluded that “if the soils had remained, even though the cities were destroyed and the population dispersed, the area might have been repopulated and the cities rebuilt. But now that the soils are gone, all is gone” (p. 10). In most cases, the more technologically advanced the civilization, the shorter its period of progressive existence and expansion (Diamond 2005; Dale and Carter 1955). Similarly, in Mesopotamia, the rich soils of the Tigris and Euphrates valleys supported some of the world’s greatest civilizations. Through the centuries, the soils have been severely eroded and today the land supports less than one-sixth of the population that lived there during its historic peak.

Dale and Carter state:

Let’s not put the blame for the barrenness of these areas on the conquering hordes that repeatedly overran them. True, those conquerors often sacked and razed the cities, burned the villages, and slaughtered or drove off the people who populated them. But while the soil and other resources … remained, the cities were usually rebuilt. It was only after the land was depleted or exhausted that the fields became barren and the cities remained dead. (1955, p. 15)

Even today, many of the world’s most severe environmental problems are a direct result of modern farming practices. These problems include soil depletion; water pollution from eroded soils, fertilizers, and pesticides; and the depletion of critical resources, including groundwater and nonrenewable energy supplies. The extent to which societies deal with these problems effectively will profoundly influence the world in years to come.

Agriculture of the future will no doubt look substantially different from the agriculture of today, and its evolution will continue to have significant societal impact. Three factors are likely to play significant roles. First, technological developments have always figured prominently in agriculture and will continue to do so. Second, the emergence of a true world economy will have massive implications for prices and production in communities throughout the world. Third, the depletion of resources and environmental change will drastically alter agriculture. Of special concern is global warming, which could
significantly alter the agricultural environment in a myriad of ways. The role of social scientists in understanding these issues will be of continued significance.

AIDS

As the twenty-first century moves forward, the HIV/AIDS (human immunodeficiency virus/acquired immunodeficiency syndrome) epidemic remains a major public health concern. As of 2006, a cure for HIV/AIDS remained to be found. While medical researchers focus their efforts on finding a cure and a vaccine, social scientists work hard to find ways to prevent the spread of HIV/AIDS. These efforts have emphasized reducing behaviors that increase the risk of exposure to HIV, such as having unprotected vaginal or anal sex and sharing needles when injecting drugs. Such efforts require an understanding of which groups of people are most at risk for contracting HIV.

During the late 1990s and early 2000s, the Centers for Disease Control and Prevention (CDC) estimated that approximately forty thousand new cases of HIV infection occurred each year in the United States. Among the 23,153 men diagnosed with HIV in 2003 (73 percent of all cases reported by thirty-three states), men who have sex with men (MSM) accounted for the largest proportion (63%), followed by those reporting heterosexual contact (17%) or injection-drug use (14%), MSM and injection-drug use (5%), and other-unspecified (1%). Among women diagnosed with HIV in 2003 (27% of all cases), heterosexual contact accounted for the largest proportion (79%), followed by injection-drug use (19%), with 2% reported as other-unspecified. While a much higher percentage of men are infected with HIV in the United States, women make up a rising percentage of those living with HIV/AIDS (their numbers increasing from 14% in 1992 to 22 percent in 2003), and heterosexual transmission has become an increasingly important factor for men.

Race/ethnicity diagnoses in 2003 were disproportionately led by African Americans (50%), followed by whites (32%) and Hispanics (15%).

Social scientists use demographic information to design and implement prevention programs specifically tailored to minimize exposure for population groups at risk for HIV/AIDS. Because each population is primarily at risk through a single but unique means of HIV/AIDS transmission, prevention programs vary tremendously in emphasis depending on the target population. Identifying and effectively targeting those at risk for HIV/AIDS are fundamental to setting up a situation in which social pre-
vention programs can be effective. The late 1990s and early 2000s have seen a variety of prevention programs, ranging from intense, individual therapy to group programs and public announcements addressing a large audience.

Three primary components of prevention programs appear most effective: providing attitudinal arguments, basic information, and behavioral skills training. Although attitudes do not always predict behavior, research has shown that certain attitudes can influence the likelihood that one engages in a certain behavior. For example, positive attitudes toward condoms are associated with more frequent condom use. Basic information made available in prevention programs typically includes discussions of how the virus is transmitted, how to evaluate one’s personal level of risk exposure, and how to prevent transmission. Behavioral skills training allows participants to practice skills related to reducing high-risk sexual behavior. Training can include skills such as discussing condom use with partners, condom application and removal, and cleaning and disinfecting needles and syringes. Although attitudinal arguments, basic information, and behavioral skills training are common components of effective prevention programs, an individual’s gender, ethnicity, age, and risk group can have an impact on that effectiveness.

Other prevention approaches have produced varied results. Programs providing only basic information have little impact on reducing risky behaviors. Fear-based approaches most often target mass audiences, but are only effective if an individual believes he or she can accomplish the desired behavior and that doing so will lead to the expected outcome. With condom use, for example, fear-based appeals only work when people believe they can use condoms and that, if they do, they won’t get HIV/AIDS.

There are several barriers to HIV/AIDS prevention efforts. These barriers include, but are not limited to, religious objections to sex education, substance use, unknown HIV status, underestimating risk, denial of sexual preference, sexual inequality in relationships, and AIDS stigma. Despite the extremely low rates of HIV/AIDS in countries with rigorous sex education programs, such as the Netherlands and Sweden, religious-based objections to sex education remain an obstacle for prevention researchers. People under the influence of alcohol or drugs are more likely to engage in high-risk behaviors, such as unprotected sexual intercourse. An additional factor in the spread of HIV is people living with HIV/AIDS who are unaware of their status, an estimated 250,000 people in the United States alone. Research has shown that a high percentage of those testing positive for HIV considered themselves at low risk for the virus. This is problematic because those who underestimate their risk of infection are less likely to engage in risk-preventing behaviors. Similarly, and particularly among African American MSM, denial of sexual preference is high. In addition to underestimating risk, these men are less likely to respond to, and thus benefit from, prevention efforts targeting MSM. Among women, perceived inequality in a relationship can reduce prevention efforts. For example, some women may fear violence or abandonment should they insist that their partners use condoms.

Perhaps the strongest barrier to prevention efforts comes from “AIDS panic” or AIDS stigma. There are three primary sources of AIDS stigma: fear of HIV infection; the labeling of risk groups (e.g., identifying AIDS as a “gay disease”); and negative attitudes toward death and dying. In addition to implementing programs aimed at reducing risky behavior, social scientists also work to eliminate stigmas associated with HIV/AIDS. By 2006, there was some evidence of positive effects from these programs; however, research in this area is limited, and the observed effects may be minor and short-lived. Nonetheless, continuing these efforts is important because of the severe negative effects stigma can have on those living with HIV/AIDS. These effects include psychological problems such as anxiety and depression, strained social relationships, abandonment by family members, loss of medical insurance, and employment discrimination.

Although most barriers to prevention are widespread, internationally the AIDS epidemic is even more troubling and the additional barriers to prevention in Africa, Asia, and third world countries have elevated the challenges facing prevention researchers. A person’s religious beliefs may discourage the use of condoms for contraceptive reasons, for example. In some countries, poor economic conditions and access to medical care or antiviral medications, coupled with an even greater social stigma associated with the virus, decrease the likelihood of persons living with HIV/AIDS seeking and receiving medical treatment. The early twenty-first century is marked by a global effort to help countries where HIV/AIDS cases are alarmingly high yet medical resources are scarce.

In the absence of a vaccine, social science offers the only effective means of preventing HIV/AIDS transmission. The 1900s and early 2000s have seen great advances in the effectiveness of prevention programs, especially those targeting specific high-risk groups. Despite these efforts, HIV/AIDS remains an international epidemic requiring an international response.

BIBLIOGRAPHY
AIDS/HIV in Developing Countries, Impact of

Developing countries include low- and middle-income economies as well as those in transition from central planning. A wide diversity of political, economic, social, religious, and cultural systems is embraced within such countries, resulting in markedly different HIV/AIDS experiences between neighbors as well as within the nations themselves.

Several HIV epidemics often operate in tandem, including injecting drug-use, unprotected heterosexual or male-to-male sexual contact, mother-to-child infection (either in the womb or by breast feeding), and contaminated blood products. Even within a country, epidemics can be extremely diverse.

Ninety-five percent of the 38 million adults and 2.2 million children estimated to be living with HIV worldwide at the end of 2005 lived in developing countries. Worst affected is Sub-Saharan Africa, where an estimated 25.8 million have the disease, including the 3.2 million new infections during 2005. South and Southeast Asia follow with 8.3 million, Latin America and the Caribbean with 2.1 million, Eastern Europe and Central Asia with 1.6 million, East Asia with 870,000, and North Africa and the Middle East with 510,000. Worldwide, 26 million people have died from AIDS and related illnesses, 3 million of these in 2005 alone.

During that year some 4.8 million adults and children were newly infected with HIV in developing countries, 98 percent of the global total. The full extent of the problem is hidden because of inadequate testing and reporting facilities in some countries and regions within them. People may not want to be tested, and continue living with HIV without being aware of it, but even if testing positive, they may not tell their partners, seek treatment, or negotiate safer sex.

THE EMERGENCE OF EPIDEMICS

Epidemics usually pass through stages, beginning with injecting drug-users sharing needles and syringes, commercial sex workers having unprotected sex with clients, and men having unprotected sex with men. As HIV spreads more widely among these groups, it begins to percolate into the wider population, as has occurred in Indonesia, Vietnam, and Malaysia. Then, when the overall infection rate exceeds one percent, as in Thailand, Cambodia, and Myanmar, the epidemic is considered to have become generalized.

In most countries high rates of infection are associated with marginalized groups like sex workers, truck drivers, and men having sex with men. Epidemics in India, Pakistan, Libya, Uruguay, and Ukraine are being driven by injecting drug-use; in the Russian Republic HIV prevalence is four times greater in prisons than in the population at large. Some groups are especially at risk. Women and girls with little income may turn to risky commercial sex. In Sub-Saharan Africa, for example, those aged between fifteen and twenty-four are three times more likely to be HIV-positive than men in a similar age group.

The origins and early spread of HIV/AIDS remain controversial but it seems to have emerged in Central Africa toward the end of the 1970s and in the United States and Europe in the early 1980s. Elsewhere it appeared later, with the first HIV cases being reported in Thailand and the Philippines in 1984, in India and the People's Republic of China in 1985, and in Myanmar in 1988. The early data are very unreliable. In 1992, for instance, estimates of total HIV infections in Thailand ranged from 333,000 to 696,000 depending on how studies of military conscripts were analyzed and varying assumptions about the age and gender distribution of the disease. In societies where religious and political leaderships had close relationships, HIV was initially explained away as an outcome of lax morals in Western societies. Sometimes there were disputes between departments, as in Thailand, where the Tourism Ministry was concerned that health authority warnings about HIV/AIDS would deter foreign visitors.

By the mid-1990s HIV/AIDS had emerged in virtually every country. The vast differences in population make raw numbers misleading. In India the 2.095 cumulative AIDS cases in adults and children reported to the World Health Organization in December 1995 represented a rate per 100,000 population of less than one, whereas the forty-three cases in New Caledonia represented a rate of twenty-five. The wide geographical spread of the disease in Asia alone can be seen from the fact that...
by 1995, 570 cases had been reported in Myanmar, 292 in Vietnam, 259 in Malaysia, and 220 in the Philippines. Actual numbers were probably much higher.

Most people living with HIV/AIDS are in the prime of their working life. Industry and commerce thus suffer from absenteeism, lower productivity, and lack of investment. Police recruitment, and the maintenance of law and order, become more difficult. Dwindling government revenues and rising expenditures (on health care, for example) can put at risk decades of development progress. In twenty-five Sub-Saharan countries average life expectancy rates have fallen dramatically since about 1988, due mainly to HIV/AIDS. Worst affected is Botswana, with life expectancy expected to fall from 60 to 27 years by 2010. In Asia, the Caribbean, and the Russian Republic steep declines are also in evidence.

In Sub-Saharan Africa there are 12.1 million orphans (80 percent of the global total), children under eighteen who have lost one or both parents to AIDS. In Nigeria alone AIDS orphans number 1.8 million and in South Africa 1.1 million. Some live with relatives or in institutions, but many end up as abused street kids who will be ill-equipped as adults to become professionals such as teachers and doctors, drive industry and commerce, or run the bureaucracy.

Often the opportunity for early intervention was missed. Thus, the Chinese government maintained that homosexuality and prostitution were not only illegal but contrary to Chinese morality. Despite warnings by health officials in 1993 that 100,000 people could be living with HIV by 2000 and 20,000 with full-blown AIDS, it was not until 2001 that the government admitted to a semi-official estimate of 600,000 infections spread over almost all parts of the country. Earlier and more vigorous intervention might have slowed the spread of the disease.

Large variations exist between individual countries, between rural and urban areas, and between men and women. Thus HIV prevalence rates are below 1 percent in Mauritania and Senegal but reach almost 40 percent in Botswana and Swaziland. Prevalence among some pregnant women in Namibia exceeds 50 percent.

In Asia the main driver of HIV infection is injecting drug-use, often accompanied by unsafe sexual practices. The huge populations of some countries reduce the average adult HIV prevalence rate to only about 0.4 percent, disguising the fact that in Asia as a whole at least 8.3 million adults and children were living with the disease in 2005. During the previous year 1.1 million people were newly infected and 520,000 died of AIDS.

In most countries several epidemics are underway: in India (which had 5.1 million people living with HIV in 2003) the disease is being mainly spread by unprotected sex in the south and injecting drug-use in the northeast. Widespread ignorance about safe sex and a growing propensity for youngsters to engage in sexual activities are further boosting the spread of HIV in countries like Indonesia, Vietnam, Pakistan, Malaysia, and Japan.

HIV/AIDS has a massive impact on societies. It places a huge financial burden on health care (even without costly antiretroviral therapy) and on medical facilities, hospitals, and nursing staff. Households and nutrition suffer when people are too ill to work, while caring for the sick reduces the time other household members can spend on activities such as farming. Children, especially girls, may be taken out of school to reduce costs or to help look after the sick, which has implications for literacy, skill development, and even dissemination of knowledge about diseases.

More than 15 million people had already died of AIDS in Sub-Saharan Africa by 2005 and, without massively expanded intervention programs and antiretroviral therapy, deaths will increase as people infected with HIV eight to ten years ago succumb to full-blown AIDS.

The AIDS epidemic continues to outstrip the global efforts to contain it. In mid-2005 only one person in ten in Africa and one in seven in Asia who needed antiretroviral treatment was receiving it. Progress is mixed. An estimated one-third of the people in need of antiretroviral treatment in Botswana and Uganda were receiving it in mid-2005, but in many African countries it is available to less than one in ten. Since 1996 Brazil has been providing free treatment, to 170,000 people in 2006, while Indian drug companies are making treatments available at more affordable prices. For most of the developing world, however, more basic initiatives are needed, with HIV/AIDS being seen as part of the wider problems of access to clean water, malnutrition, poverty, discrimination, and unemployment. Much has to be done to educate people, especially women and those living in rural areas, about this and related diseases and ways of avoiding them, but perhaps only one in ten people living with HIV has been tested and knows that he or she is infected.

AINSWORTH, MARY
1913–1999

It is difficult to overestimate the influence Mary D. Salter Ainsworth has had on the field of developmental psychology. Her work has been cited by over 7,000 social science sources, with over 2,500 of these citing her seminal work on patterns of infant attachment (Ainsworth, Blehar, Waters, and Wall 1978). Moreover, her professional life, which spanned five decades and three continents, exemplifies the gendered and circuitous career path taken by many women.

Mary Salter was born in 1913 to parents who were both college graduates. Her family moved to Toronto, Canada, when she was five, and it was there that she received her PhD in psychology from the University of Toronto in 1939, did her World War II (1939–1945) service in the Canadian Women's Army Corps, and accepted a postwar teaching appointment at her alma mater in the area of personality psychology. William Blatz, first as dissertation advisor and then as colleague, influenced Mary Salter's research interests in the contribution of a secure relationship between parent and child to healthy growth and adjustment.

Marriage to Leonard Ainsworth, a graduate student at the University of Toronto, complicated her staying at the university as a faculty member. The couple relocated to England in 1950 when Leonard was accepted to a doctoral program at University College, London. Mary Ainsworth soon began a research position at the Tavistock Clinic with John Bowlby, who was using evolutionary and ethological theory to explore the development of attachments to caregivers and the consequences of maternal separation and loss for young children.

In 1954 Leonard Ainsworth accepted a job at the East African Institute of Social Research in Kampala, Uganda. Mary Ainsworth moved to Africa with her husband and secured an appointment at the Institute. She then embarked on a longitudinal field-based study of infant-mother interactions in their natural setting using the skills she had developed in analyzing naturalistic observations at Tavistock. The commonalities she observed in the developing relationships of Ugandan infants to their mothers and the attachment development of infants in industrialized nations was striking to Ainsworth and consistent with Bowlby's theoretical explorations. When the Ainsworths returned to the United States at the completion of Leonard's two-year appointment, Mary brought back extensive field notes. A decade later these became the basis for her book Infancy in Uganda (1967), which provided much of the first empirical evidence supporting Bowlby's ethological theory of attachment development and in general made a significant contribution to the emerging field of infant social development.

On returning from Africa, Mary Ainsworth obtained a teaching and clinical position at the Johns Hopkins University. She also began to organize an intensive observational study of infant-mother pairs in Baltimore from birth through age one. In a series of papers, Ainsworth examined the sensitivity and responsiveness of mothers across a variety of daily contexts, such as feeding, face-to-face interaction, greetings, explorations, and the exchange of affection. She found connections between individual differences in maternal sensitivity and an infant's later responses to a series of separations and reunions from his or her mother. Compared to infants of less responsive mothers, infants of more responsive mothers evidenced more secure maternal attachment in their reaction to separation and reunion.

To quantify the infant's attachment security, Ainsworth and her colleagues developed a twenty-minute procedure (known as the Strange Situation) involving a series of separations and reunions between mother and toddler. Three main patterns of attachment were observed: (1) anxious/avoidant, in which the child tended not to be distressed at the mother's departure and to avoid her on return; (2) securely attached, in which the child was distressed by mother's departure and easily soothed by her on return; and (3) anxious/resistant, in which the child tended to become highly distressed at the mother's departure, only to seek comfort and distance simultaneously on her return by engaging in behaviors such as crying and reaching to be held, but then attempting to leave once picked up.

The Strange Situation has become one of the most commonly used procedures in child development research, and it has been extended to studies of attachment behaviors and correlates in rhesus monkeys, chimpanzees, and dogs used as pets and guide animals for the blind (Fallani, Prato-Previde, and Valsecchi 2006; Inoue, Hikami, and Matsuzawa 1992; Prato-Previde, Fallani, and...
Valsecchi 2006; Stevenson-Hinde, Zunz, and Stillwell-Barnes 1980). Ainsworth’s original interpretations have also prompted several lines of research to explicate the origins and meanings of behavior in the Strange Situation (e.g., Mangelsdorf, McHale, Diener, et al. 2000; Marshall and Fox 2005).

Mary Ainsworth moved from Johns Hopkins to the University of Virginia in 1975. She died in 1999, leaving behind forty published papers or books and scores of investigators whose work is securely attached to her own.

AKERLOF, GEORGE A.

1940–

American economist George Akerlof received the Bank of Sweden Prize in Economic Sciences in Memory of Alfred Nobel in 2001. He was awarded this prize jointly with economists Michael Spence and Joseph Stiglitz, for their work on asymmetric information—a situation in which agents in a market have differing levels of information (e.g., regarding the quality of a product). In his seminal paper “The Market for ‘Lemons’: Quality Uncertainty and the Market Mechanism” (1970), Akerlof demonstrates how asymmetric information is persistent in the market for used cars. In the simplest example, there are two types of cars: a high-quality car with price $C^h$ and a “lemon,” or defective car, with price $C^l$. Only the seller is aware of the type of car being sold, whereas the consumer faces significant uncertainty about the quality of the pur-
chase. Given that the probability of receiving a car of high quality is \( q \), where \( 0 < q < 1 \), and low quality is \( 1 - q \), the buyer will only be willing to pay the expected value of the car, or \( q \cdot C_h + (1 - q) \cdot C_l \). As a result, lemons will drive owners of high-quality cars, who have little incentive to sell at the average price, out of the market. Akerlof also suggests that institutions, such as warranties and chain brands, may help circumvent the problem of asymmetric information. Despite critical acclaim for this work, some researchers have criticized Akerlof’s theoretical model for its failure to explain observed empirical patterns.

Akerlof has also made significant contributions to the understanding of efficiency wages—that is, wages set above the market-clearing wage as a way to induce worker efficiency and productivity. In 1967 Akerlof spent a year at the Indian Statistical Institute in New Delhi as a visiting professor. He describes what he learned in India during that time as “the keystone for [my] later contributions to the development of an efficiency wage theory” (2001). Almost twenty years after his return from India, he published “Efficiency Wage Models of the Labor Market” (1986), written with his wife, economist Janet Yellen. This paper explains the motivation behind efficiency wages, which are an oft-cited theoretical explanation for market failures resulting in involuntary unemployment. Akerlof and Yellen show that firms pay efficiency wages because they minimize the labor cost per efficiency unit.

Akerlof was born on June 17, 1940, in New Haven, Connecticut. He attended high school at the Lawrenceville School in Princeton, New Jersey, and in 1958 entered Yale University, where he earned his BA degree. He later attended the Massachusetts Institute of Technology, from which he received a PhD in economics in 1966. He has been a visiting professor at the Indian Statistical Institute (1967–1968) and the Cassel Professor of Money and Banking at the London School of Economics (1978–1980), and has also served as senior economist at the Council of Economic Advisers (1973–1974). Akerlof is currently Koshland Professor of Economics at the University of California, Berkeley.

AL JAZEERA

Al Jazeera satellite television was founded in 1996 in Doha, Qatar. Within less than two years of its founding, it dramatically transformed the media and information climate in the entire Arab world. The station capitalized on the emergence of satellite reception in the Arab world from the early 1990s, which created potentially large regional markets that began to be filled up by commercial and state-owned stations. When Al Jazeera was launched, it was clear that no Arab government was willing to tolerate uncensored news media. The founding staff of Al Jazeera was in fact recruited from the ranks of an earlier British Broadcasting Corporation Arabic television service that had been set up in Saudi Arabia, but that had its contract canceled because of the Saudi government’s objection to its editorial content.

Conceived as an independent station but supported with loans or grants from the then new, reform-oriented emir of Qatar, Hamad bin Khalifa Al Thani, the station devoted itself to news and information, and became known for a daring style in which it presented issues that would have been routinely censored by any Arab government. It interviewed opposition figures and members of banned parties. It moved away from the traditional news format of staid, official news, focusing instead on items relevant to a wide pan-Arab audience. Almost all Arab governments levied complaints against the station with the government of Qatar at one point or another. The Saudi government went a step further, banning companies that advertise on Al Jazeera from operating in the country. In this way it attempted to economically undermine what seemed to be, for a few years, the freest channel of information with a pan-Arab audience. The station also drew bitter complaints from the U.S. government over its graphic coverage of the wars in Iraq and Afghanistan, as well as for allegedly inflaming Arab feeling by its equally poignant coverage of the suffering in the occupied Palestinian territories. During the Afghanistan and Iraqi wars, U.S. aircraft in fact bombed and destroyed Al Jazeera’s offices in Kabul and Baghdad, killing some jour-
nalists, and in both cases the official story was that the bombings were mistakes.

Realizing that Al Jazeera was here to stay, many commercial as well as government-owned channels in the Arab world changed their formats or saw some relaxation of rigid censorship so as to compete with Al Jazeera, which by 1998 had become the most widely watched station in the entire Arab world. Even the Saudi government, once the station's severest critic, set up al-Arabiyya, a competing satellite station that mimicked Al Jazeera's style of uncensored news and reporting. In view of the station's association with the emir of Qatar and its location in that country, its coverage of Qatar appears scant, although the country itself is small and is of little importance in the context of the more pressing pan-Arab issues.

In addition to news and investigative reporting, Al Jazeera also broadcasts programs on religion and modern life, featuring modernizing and popular Muslim clergy, and provides historical education in the form of lengthy interviews with "witnesses of the age," namely important intellectuals and former government or revolutionary figures. Al Jazeera regularly interviews U.S. ambassadors, secretaries of state, and other notables from around the world and was the first Arab channel to interview Israeli officials.

ALCOHOL MYOPIA
SEE Steele, Claude M.

ALCOHOLISM
While those individuals who consume alcohol to the point of abuse or dependence comprise only a small percent of the general public, the impact of their actions is relatively broad, as it can be felt by families, friends, and even communities as a whole. In other words, alcohol abuse and dependence on alcohol have implications not only for the health and welfare of individual drinkers, but also for the lives of persons around them. Alcoholism is therefore an important public health concern, the symptoms and effects of which are crucial to understand.

To identify alcoholism and distinguish it from alcohol abuse, researchers and clinicians in the United States typically rely on diagnostic criteria found in the American Psychiatric Association's Diagnostic and Statistical Manual of Mental Disorders. Alcoholism, or more appropriately alcohol dependence, is a chronic disease that endures throughout an affected individual's lifespan. Typically, dependence is suspected when alcohol use is coupled with the following warning signs or symptoms:

1. The strong urge or compulsion to consume alcohol. An individual experiencing such craving spends a great deal of time obtaining and using alcohol, as well as recovering from its effects.
2. Loss of control over drinking habits. When this symptom is present, individuals can no longer limit their consumption or cease drinking once beginning. Alcohol is consumed in greater quantities and over longer periods of time than intended, and there are frequent failed efforts to cut down on or control alcohol use.
3. Tolerance to the effects of alcohol. In this phase, markedly increased quantities of alcohol must be consumed in order to experience intoxicating effects (i.e., get "high"); if the amount of alcohol consumed remains constant, a noticeably diminished effect is experienced.
4. Physical dependence. This state is characterized by withdrawal symptoms, such as anxiety after drinking has stopped, nausea, and shakiness; alcohol is consumed in order to alleviate or avoid these physical manifestations.

Individuals who do not meet the diagnostic criteria for alcohol dependence, but drink despite recurrent physical, psychological, interpersonal, legal, or social problems resulting from their drinking behaviors, are categorized as alcohol abusers. It is important to note that someone who abuses alcohol may not necessarily be an alcoholic or ever develop alcohol dependence; however, an alcoholic is an alcohol abuser.

THE EFFECTS OF ALCOHOLISM ON THE DRINKER
Individuals who are dependent on alcohol expose themselves to numerous conditions that threaten the quality of
their lives. For example, because the liver is the human body’s primary organ responsible for metabolizing (i.e., eliminating) alcohol, it is particularly susceptible to alcohol-related damage. Injury to the liver due to heavy alcohol consumption is termed alcoholic liver disease (ALD) by researchers. ALD encompasses three stages or conditions: (1) steatosis (or “fatty liver”); (2) alcohol hepatitis; and (3) the most commonly known, cirrhosis.

While the first stage of ALD, steatosis, can occur after only a few days of heavy drinking, it can be reversed once drinking ceases. The second and more serious stage, alcohol hepatitis, occurs after longer periods of heavy drinking. The National Institute of Alcohol Abuse and Alcoholism equates the following indicators with alcoholic hepatitis: lack of appetite, nausea or vomiting, abdominal pain, fever, and jaundice. This condition can be potentially life threatening. If heavy alcohol consumption continues, inflammation due to alcoholic hepatitis will eventually lead to the final stage of ALD, cirrhosis. Cirrhosis is characterized by fibrosis, also known as scar tissue. As a result of continued abuse of the liver, scar tissue forms and takes the place of healthy liver cells. Consequently, the liver loses its ability to perform essential functions. The presence of alcoholic hepatitis is a tell-tale sign that cirrhosis could shortly follow.

Cognitive impairment (i.e., brain damage) is another potential consequence of alcohol dependence. Many alcoholics exhibit mild to moderate deficiencies in their intellectual performance, along with alterations to brain-cell activity in various sections of the brain. A very small percentage of long-term, heavy drinkers develop overwhelming, irreversible brain-damage conditions such as Wernicke-Korsakoff syndrome. This amnesic disorder is characterized by the inability to acquire new information or form new memories. Numerous other conditions such as gastrointestinal problems, heart disease and stroke, and carcinoma have also been associated with alcohol dependence.

THE EFFECTS OF ALCOHOLISM ON SOCIETY

In addition to documenting the damaging and potentially life-threatening consequences of alcohol dependence for the individual drinker, researchers have also identified numerous impacts of alcoholism that affect those surrounding an alcoholic. Often referred to as social consequences, these include:

1. The impact on communities: Intoxication can lead to unintentional accidents—such as automobile crashes and fires—as well as to criminal behavior or disorderly conduct, such as violence toward others and vandalism.

2. The impact on families: Alcoholics may neglect familial responsibilities, such as caring and providing for children or spouses; if they exhibit violent or aggressive behavior, this may lead to marital conflict, child or spousal abuse, or divorce. If maternal alcohol consumption occurs during pregnancy, serious birth defects such as fetal alcohol syndrome may develop.

3. The impact on the workplace: Alcoholism can result in lost workplace productivity due to time-off for alcohol-related illness or injury, in termination due to decreased job performance or absenteeism, and in increased company costs when termination makes it necessary for new employees to be recruited and trained.

OVERCOMING ALCOHOL DEPENDENCE

While some of the damage caused by alcohol dependence cannot be reversed, there are numerous treatment options available to alcohol-dependent individuals that may allow them to return to a more balanced and healthy lifestyle. It is important to note, however, that alcoholism cannot be cured. Alcoholics cannot address their affliction and the effects they experience by “cutting back” on the amount they consume. If actual progress is to take place, it is essential that an alcoholic “cut out” any and all drinking. Thus, to guard against relapse, alcoholics must avoid any contact with alcoholic beverages. Permanent sobriety is a long and arduous road; however, there are treatment options available that have shown promise in helping individuals to remain sober.

Adam E. Barry
ALGER, HORATIO
1832–1899
Horatio Alger Jr. is the author most closely associated with the American rags-to-riches story. His name has become synonymous with the experience of rising from relative poverty to substantial fortune without an inheritance; such a trajectory is often termed a “real Horatio Alger story.” The son of a Unitarian minister living in Revere and Marlborough, Massachusetts, Alger graduated from Harvard University in 1852 and from the Harvard Divinity School in 1860. The Harvard Unitarians were heirs to the Calvinists, the Puritans, and the Congregationalist tradition. The Unitarians were steeped in a belief in the importance of character and the role of both the individual and the community in maintaining the character and ethical sensibility in the young. At Harvard, Alger studied Greek and Latin and read Scottish common-sense philosophers such as Francis Bacon and Thomas Reid. The Harvard Unitarian moralists of the antebellum era sought to render Plato’s teachings compatible with Christianity, and as Alger saw it, Socrates believed in divine retribution for earthly sinners. Alger also studied with the poet Henry Wadsworth Longfellow (1807–1882) and later sought his favor when he published his own volume of adult poetry in 1875. One of Alger’s mentors was Harvard president Edward Everett (1794–1865).

Alger served briefly as a minister in Brewster, Massachusetts, but left the ministry in 1866 and moved to New York City to earn his living by his pen. An author of modest literary talent, Alger wrote fiction aimed at pleasing large audiences, but amassed no riches in doing so. In addition to writing, Alger also tutored the sons of wealthy New Yorkers, including those of the Seligman and Cardozo families. Alger published 123 works as novels, serializations in newspapers and magazines, and books of poetry. Most of his formulaic fiction was aimed at juvenile readers. Alger created nineteenth-century characters who are “risen from the ranks,” who “strive and succeed” and are “bound to rise”; they manage to transform themselves with “luck and pluck” and with the help of benevolent mentors from bootblacks, newsboys, or street peddlers to respectable adults with comfortable middle-class incomes. Some late heroes attain more remarkable fortunes, particularly in the era of the robber barons. Several novels feature heroines, such as Jenny Lindsay, the title character in Tattered Tom, who is saved from street life before she attains adolescence. Quite a few heroes leave New England farms and villages where their families cannot support them and go to the big city, but some heroes depart for Western adventures and one is sent, with the help of the Children’s Aid Society, from the city to the countryside to be brought up in a healthier environment.

Alger kept his heroes out of the way of modern factory labor. Genteel moralists of his era believed that manliness required independence; factories were seen as both breeding dependence and bringing the young into contact with fellow workers who endangered virtue. Alger’s most famous and popular work, Ragged Dick, was published in 1867 and featured a young, spirited, cheerful but ragged orphan bootblack who captures the attention of a benefactor who helps him attain middle-class respectability. Alger asserted that his story Phil, the Fiddler, featuring a very young Italian street musician, helped to end the exploitive padrone system, a system that involved the near-enslavement of young children brought from Italy to work for the benefit of those to whom they were contractually bound. The author befriended and assisted various young boys, and informally adopted at least two of them.

Alger heroes not only work hard and help themselves but also possess steadfast character, are loyal to their employers, and help others along the way who are deserving. In Alger’s formula, character is capital. Its value is recognized wherever it goes. Stories arrange for accidents through which the character of the struggling young person comes to the attention of a benefactor. Foils are excessively focused on money, social status, and finery; they consume but do not produce, and have no fellow feeling. Alger’s morality tales frequently arrange justice for such characters. These stories not only provided graphic detail of neighborhoods of New York but also told readers how to avoid crime and confidence games. However, by the 1890s, some moralists inveighed against juvenile fiction, including Alger’s, for planting false ideas of life in the heads of impressionable young people, encouraging them to leave their homes for adventure in the city or out West. Many libraries removed Alger novels in this period.

The fiction of Horatio Alger Jr. fueled the American dream of rising through the ranks and becoming self-made. Poverty was not an insurmountable barrier to success, and character—a key ingredient of success—was under one’s own control. Many Americans would subsequently conclude that failure was the individual’s own fault. While it was appropriate for charitable organizations and benevolent individuals to help deserving young people along the way, for quite a few Americans the self-help creed precluded public, governmental efforts to address poverty and inequality.

ALI, MUHAMMAD (MEMET)
1769–1849

The history of modern Egypt opens in 1798 with Napoleon Bonaparte’s (1769–1821) invasion of the Ottoman province, destroying the army of the Mamluk rulers at the Battle of the Pyramids. With the Mamluks and the Ottomans in disarray, the French troops also withdrew after the defeat of the French fleet at Abu Qir, leaving a political vacuum. Muhammad Ali (or Mehmet Ali), born in the Macedonian town of Kavalla in the Ottoman Empire, was a young officer serving with the Albanian contingent against the French. He successfully filled this vacuum by creating a power base in the villages, and by joining forces with local clerics and merchants in Cairo. He removed three successive governors sent from Istanbul. Appointed wali or Ottoman viceroy of Egypt in 1805, Muhammad Ali used brutal methods to establish his control over Egypt, including breaking the power of the Mamluks by massacring their leaders in 1811. Regarded as the founder of modern Egypt, he created a dynasty that ruled Egypt until 1952.

Recognizing that modern political power rests on a modern, disciplined army, Muhammad Ali conscripted peasants from Upper Egypt to train them in the Napoleonic army system. He undertook a number of military campaigns, but his military and dynastic ambitions were thwarted by British, French, or Russian intervention. These powers had their own designs on the dismemberment of the Ottoman Empire, and their interests were not compatible with the strategic objectives of Muhammad Ali. Between 1820 and 1822, he conquered the Sudan in search of gold and slaves, founding the city of Khartoum in 1823. Some thirty thousand Sudanese slaves had been trained, and these nizami troops, led by Muhammad Ali’s son Ibrahim (1789–1848), were sent against the Greeks in 1827 in the Greek war of independence. Although his troops were relatively effective, the Ottoman navy was destroyed at the Battle of Navarino in 1827.

To fund his military reforms, Muhammad Ali established long-staple cotton as a cash crop and modernized Egyptian agriculture for cotton production to supply the British textile industry. To secure his rule and to support cotton production, he confiscated the lands of the ruling class, made large land grants to his own family, and reclaimed uncultivated land, thereby creating a new landed class to support his political rule.

His modernization program also included the reform of educational institutions, the creation of a teaching hospital, the building of roads and canals, the construction of state factories, and the development of a shipbuilding foundry at Alexandria. These industrial developments provided the military platform that led Muhammad Ali to invade Greater Syria in 1831 and again in 1839. Alarmed by his success, the British intervened, blocked the Nile Delta and defeated him at Beirut. In the Treaty of London in 1841, he surrendered Crete and Hijaz and abandoned his military ambitions; in return, he and his descendants were given hereditary rule over Egypt. He died in 1849, being buried in the Muhammad Ali Mosque in the Citadel of Cairo, the mosque that he had commissioned.

Muhammad Ali was the last of the military adventurers who periodically seized power in the Ottoman provinces, giving their military domination a mask of legitimacy by creating a dynasty. He was fortunate to rule in a period of Ottoman decline, taking advantage of French military officers to modernize his army.

Bryan S. Turner

ALI, MUHAMMAD (USA)
1942–

Muhammad Ali was one of the greatest heavyweight boxing champions. He also stands as a powerful symbol of
social and cultural change in the United States during the second half of the twentieth century.

Ali was born Cassius Marcellus Clay Jr. in Louisville, Kentucky, on January 17, 1942. He began boxing at an early age and had a distinguished amateur career that culminated in winning a gold medal at the 1960 Rome Olympics. He then turned professional, and on February 25, 1964, he defeated Sonny Liston (1932–1970) to become heavyweight champion at the age of twenty-two.

Already at this point in his career Ali demonstrated the outspoken demeanor that reflected the changing racial climate of the times. The civil rights movement that had begun in the United States in the years following World War II (1939–1945) was coming to a climax, with widespread activism, the charismatic leadership of Martin Luther King Jr. (1929–1968), and the passage of landmark federal legislation, including the Civil Rights Act of 1964 and the Voting Rights Act of 1965. The more violently confrontational Black Power movement was about to begin. The history of the heavyweight championship and Ali's role in it serves to reflect these elements of change. Following a controversial black champion, Jack Johnson (1878–1946), in the early years of the century, no African American was allowed to fight for the heavyweight championship until the arrival of Joe Louis (1914–1981) in the 1930s. Louis, who held the title from 1937 to 1949, and other black champions who followed, most notably Floyd Patterson (1935–2006) during the late 1950s and early 1960s, were submissive and noncontroversial. The young Cassius Clay, however, was brash and outspoken. Shortly after becoming heavyweight champion, the aura of controversy surrounding him grew when he announced that he had become a member of the Nation of Islam and was officially changing his name to Muhammad Ali. In 1966, as U.S. military involvement in Vietnam became an increasingly divisive national issue, Ali announced that he was seeking exemption from military service as a conscientious objector. As a result of this, and his subsequent refusal of induction when his draft board failed to grant the exemption, he was formally stripped of his boxing title early the following year.

Ali was kept out of the sport for next three years. In 1970, however, he was again able to obtain a boxing license, and in 1971 the U.S. Supreme Court overturned his conviction for refusing induction. Returning to the ring at the age of twenty-eight, he went on to fight some of his most memorable bouts, including his stunning victory over George Foreman in Zaire in October 1974 in which he regained the heavyweight title. He continued to fight through the rest of the decade, losing and regaining the title a third time in 1978. He fought his last fight and left the ring for good in 1981.

In the latter part of his fighting career, Ali began to display the effects of his many years in boxing. In the early 1980s he was diagnosed with pugilistic Parkinson's syndrome. Despite deteriorating health following his retirement, he continued to make public appearances and to serve as a spokesperson for anti-imperialist and anticolonial movements throughout the world. During this period also, his reputation in the United States gradually underwent a transformation, from a figure of controversy to a national icon. In 1980 he was sent to Africa by President Jimmy Carter in an unsuccessful effort to gain African support for the U.S. boycott of the Moscow Olympics. A diplomatic effort in Iraq in 1990 secured the release of several of the U.S. hostages being held by Saddam Hussein (1937–2006) in the period immediately preceding the 1991 Gulf War. As the 1990s progressed, Ali's rise to iconic status continued. In 1996, with an estimated three billion people around the world watching on television, he lit the Olympic flame to open the Atlanta Summer Olympics, and nine years later, in 2005, he was awarded the Presidential Medal of Freedom at a ceremony in the White House.

It is extremely difficult to separate the real from the mythic Ali. His stature, clearly, extends far beyond his skill in the boxing ring, and is attributable to the natural charisma and sincerity of the man, to the work of the many journalists and publicists who wrote about him, and finally to the times in which he lived. Never a profound or original thinker, Ali's activities and pronouncements on various issues—his support, for example, of Republican presidential candidates Ronald Reagan (1911–2004) and George H. W. Bush in the 1980s—often appeared inconsistent and contradictory. In the end, however, it is in the transition from a figure of controversy to a national icon, and the manner in which it serves to symbolize the social and cultural change occurring in the United States during the second half of the twentieth century, that his greatest significance lies.

BIBLIOGRAPHY
ALIENATION

Alienation is a term that is employed commonly in a number of disciplines to describe and explain the sense of estrangement that organizes the relationship between the subject and itself on the one hand and the subject and its relationship to history, power, and authority on the other hand: estrangement from the state in Georg Hegel, from God in Ludwig Feuerbach, from labor in Karl Marx, or from essential sexuality in Sigmund Freud. Anthropology, philosophy, economic theory, sociology, and political science all refer to the tensions that result from the sense of alienation experienced by the subject. The word alienation, however, comes from the Latin term alius, meaning “other” or “another,” from which the term alienus, meaning “of another place or person,” is derived. In this way the meaning of alienation has a spatial and existential significance. In the fifteenth century it came to mean the loss of mental faculties and thus the presence of insanity, and by the mid-nineteenth century physicians who concerned themselves with mentally disturbed patients were called alienists.

Alienation is a developmental process in Hegel’s The Phenomenology of Mind (1807) and in 1844 writings by Marx that engage two gestures: Entfremdung (estrangement) and Entäußerung (externalization). The “unhappy consciousness” of Hegel is unhappy precisely because it is conscious of its own divisions, of its alienated relationship to its world, and thus cannot attain the unity that it seeks. In the ideality of the state this unhappy consciousness materializes itself as a subject. In Marx, labor itself is an object from which the worker is alienated, a realization that becomes possible only through the development of class consciousness. This materialization of the subject in late Marx (Grundrisse [1887] and Das Kapital [1857–1858]) through the experience of alienation from the labor process acquires a materiality that is expressed in Vergemeinschaftlichung (reification), enabling the transformation of Hegel’s idealism into Marx’s materialism, a point that later, as reification, acquires centrality in the work of Gyorgy Lukács and the Frankfurt School.

In Marx the worker experiences the object of his or her labor as alien and threatening so that, despite the fact that it has been produced through the worker’s labor, it is not accessible to the worker. For Marx abstracted forms of consciousness such as religion are symptomatic of the alienating experiences of workers, and only through the recognition of those forms as symptomatic of a frustrated historical experience, along with the abolition of capitalist ownership of the means of production that will interrupt the alienation of the worker from his or her labor, can they be overcome and allow for the emancipation of the subject.

For Feuerbach (1841) religion constitutes the alienated form of human realization of the divided subject. This is a process in which the subject understands itself as having been alienated from its own human essence and has turned that essence into an abstracted object of worship. In Future of an Illusion ([1928] 1975), Moses and Monotheism (1938), and Civilization and Its Discontents [1930] 1962), Freud recognizes civilization as the location where the understanding of the frustrated relationship of the subject with itself takes place. The overcoming of the sense of alienation is engendered either by the recovery of the subject’s relationship to the divine (in the theological tradition) or by the recovery of the libido (in Freud). However, since alienation belongs to the historical process of subject formation and recognition, a process that reveals as much as it constitutes the process of civilization itself, alienation is taken to be the ransom of civilization, a point of no return (to nature or essence) for the human subject.

In the work of the Frankfurt School, particularly in that of Theodor W. Adorno (Horkheimer and Adorno [1944] 1972), alienation is the result of the rationalization of the process of cultural production, a process that is analogous to the injustice that is produced through the rationalization of the market. In that sense Adorno sees alienation not as part of the process of subject formation that has within it the potential for emancipation, as Marx saw it becoming as part of the historical process, but as constitutive of the new, modern subject that rests on reason, a reason that in modernity has become bankrupt without any prospects of resistance.

See also Alienation-Anomie; Consciousness; Frankfurt School; Freud, Sigmund; Hegel, Georg Wilhelm Friedrich; Lukács, Georg; Marx, Karl; Power; Religion; Sexuality

BIBLIOGRAPHY

**ALIENATION-ANOMIE**

Since 1844, when Karl Marx (1818–1883) first used the concept, alienation has been an important instrument for social critique. Marx saw alienation as inevitable in a capitalist social order where workers were paid for the time they spent producing commodities whose value for market rests on the labor congealed within, but the worker gets very little of the market price. For the capitalist who sells the goods for profit, the accumulation of wealth is the primary value. When, however, workers sell their time as a commodity, they too become commodities—they become alienated, that is, both objectified and estranged. In producing commodities, workers are rendered powerless and their lives meaningless. They are estranged from their “species being,” the innate human ability to see themselves as members of a species. Their creativity and humanity are thwarted and their social world is fragmented. Marx understood alienation as a multidimensional concept with implications for the social structure and for groups and with psychological consequences for individuals.

The discipline of sociology emerged with the tumultuous changes consequent on the French Revolution (1789–1799), industrialization, and urbanization. Avoiding a political stance, sociologists explained the upheavals in different ways. Max Weber (1864–1920) explained the process of modernization as one of relentless rationalization that trapped people in the “iron cages” of bureaucratic organization. For Georg Simmel (1858–1918), people could have little concern for one another in the superficial anonymity of urban life. For Émile Durkheim (1858–1917), the erosion of social bonds meant that people were isolated and lonely. When they could not adjust to the emergent values of a modern society, with its high division of labor and advanced technologies, they were subject to anomie, normlessness.

Sociologist Robert K. Merton (1910–2003) explored modes of response to anomie and alienation by devising a typology for different kinds of fit between cultural goals and the institutionalized means available for realizing them. When goals and means are upheld, a group demonstrates conformity, while rejection of both signals 

*retreatism* (a withdrawal into mental illness or addiction). Two additional types of adaptation are *innovation*, developing new means to attain agreed-upon goals, and *ritualism*, remaining fixated on means while rejecting culturally sanctioned goals. *Rebellion* is the name Merton gave to the search for new goals and means. Stemming from alienation and unrest, rebellion can feed into movements for a different kind of society.

In the late twentieth century, there was a renewed interest in alienation as a tool for critiquing globalization. Alienation and unrest, rebellion can feed into movements for a different kind of society. Displaced from their social moorings by global changes while facing assaults on their values, alienated people tend to resort to religious fundamentalisms and resurgent nationalisms to gain a sense of stable identity, community, and meaning. For others, consumerism and popular culture feed upon alienation, at once containing discontent and reproducing the conditions that lead to this discontent. This is not new, for the advertising industry has long exploited feelings of loneliness and frustration in order to sell goods that promise to ameliorate alienation. But there are some indications of how alienation can be overcome. Many people unite to effect liberation in movements that celebrate, for example, feminism, environmentalism, and global justice.

Formulated in the nineteenth century, the concept of alienation remains a fruitful tool for understanding the contemporary world. Rooted in Marx’s critique of wage labor, the concept has been expanded to consider culture, political trends, and grassroots movements, as well as aspects of everyday life. As long as changing social conditions sustain unequal power and wealth, alienation and loneliness are likely to thwart creativity and neutralize people’s power to change. And sociologists will be there to chart the expression of alienation and how we may try to overcome it.

ALLENDE, SALVADOR
1908–1973
Salvador Allende Gossens was the democratically elected socialist president of Chile from 1970 until his death during a military coup d’état on September 11, 1973. Allende was born in Valparaíso on June 26, 1908, to an upper middle-class family. He trained at the University of Chile as a medical doctor, but he became involved in politics as a student and spent most of his adult life in politics. He was elected to the lower house of congress in 1937, served as minister of health from 1939 to 1942, and was elected to the senate in 1945. He ran for president in 1952, 1958, and 1964, and finally won in 1970 as the leader of a coalition of leftist parties, called Popular Unity.

As president, Allende sought to lead the country through a peaceful electoral transition to socialism, an endeavor known as the via chilena, or Chilean path. Popular Unity’s ambitious platform called for state control of much of the economy. The Chilean path was premised on nationalizing key industries such as copper. In addition, Allende accelerated the agrarian reform program initiated by the prior Christian Democratic government, promoted the creation of public-private firms, and vowed not to interfere in the affairs of small businesses, which were numerous in Chile. Allende also promised to improve the access of poor Chileans to education and health care.

The failure of Allende’s via chilena has inspired fierce debate among scholars. Many critics emphasize that Allende was a minority president who won only a plurality of the vote in 1970. However, minority presidents were common in Chile, with only Eduardo Frei Montalva (1911–1982) of the Christian Democratic Party winning a clear majority in the modern era (55% of the vote in 1964). In addition, the platform of the Christian Democrats in 1970 was similar to that of Popular Unity. Julio Fauández suggests that a clear case can be made that “in 1970 more than two-thirds of the electorate voted in favor of radical reform” (1988, p. 180).

Some scholars argue that Allende’s policy mistakes led to the coup. For example, Paul Sigmund (1977) questions the legality of Popular Unity’s nationalization policies and emphasizes Allende’s tactical error of failing to form a coalition government with the Christian Democratic Party, which would have ensured an electoral majority. Other scholars, such as James Petras and Morris Morley (1975), emphasize the role of the opposition (including the U.S. government) in thwarting Allende’s policy objectives.

While scholars disagree over what ultimately caused the 1973 coup, there is a virtual consensus that the U.S. government and several large U.S.–based American businesses were determined to prevent Allende from being elected and once in office sought to destabilize his government. Allende had nearly won the presidency in 1958 as the leader of a leftist coalition. Fauández (1988) notes that Allende’s near victory led to an unprecedented degree of U.S. intervention in Chilean politics. From 1958 to 1970, the U.S. government financially supported the electoral campaigns of Christian Democratic Party candidates. The United States also helped establish conservative think tanks and helped produce and disseminate popular media criticizing a hypothetical Allende administration. In fact, Fauández notes that from 1958 to 1970, the opposition to Allende (Christian Democrats, conservatives, and the U.S. government) worked hand-in-hand to prevent an Allende victory.

In spite of these efforts, the opposition was divided in 1970 and Popular Unity won. Once Allende was elected, Henry Kissinger, President Richard Nixon’s (1913–1994) secretary of state, famously quipped, “I don’t see why we need to stand by and watch a country go Communist due to the irresponsibility of its own people” (Fauández 1988, p. 182). U.S. government documents included in the Senate report Covert Action in Chile, 1963–1973 (1975) clearly show that Nixon and Kissinger, working with the Central Intelligence Agency, actively sought to prevent Allende’s confirmation as president by the Chilean
Congress in 1970 and worked to destabilize the Allende government until its demise in 1973. That said, critics of Allende and some analysts who supported the via chilena (e.g., Roxborough et al. 1977) have argued that even if the U.S. government had played no role in ousting Allende, the Popular Unity government would have failed due to its own mistakes and the fierceness and unity of the opposition.

At the end of an intense battle against military forces, Allende asked those who fought alongside him to evacuate La Moneda, the presidential palace. Rather than face capture, or likely execution at the hands of the military, Allende committed suicide. In the days leading up to the coup, Allende swore to his supporters that he would die defending his presidency and, more importantly, democracy in Chile. The military government that overthrew Allende ruled Chile from 1973 until 1989, when the dictator Augusto Pinochet stepped down after a popular referendum. During and after the coup, thousands died and thousands more were tortured.

Why was the U.S. government so intent on preventing an Allende victory? On one hand, the zero-sum game of politics during the cold war dictated that success by leftists anywhere was a threat to the United States. Thus, the via chilena had to be undermined to maintain the status quo between the United States and the Soviet Union. However, a more plausible explanation might lie in the fact that Allende and other Latin American leftists posed a threat to the hegemonic development model for Latin America and the third world, which favored large multinational firms. Allende and other leftist leaders emphasized that the region needed development models that benefited their countries and the poor. Key to this endeavor was limiting the repatriation of exorbitant profits by U.S.–based companies. The U.S. government was determined to protect the interests of U.S.–based companies and also to undermine a new socialist government in the hemisphere.

ALLIANCES

Alliances are a primary form of international relations (IR) and national security policy. In conventional usage, an alliance is a formal agreement between governments to provide military support under specific political conditions. This may include military operations separately planned and executed, or highly coordinated and integrated, and other measures such as arms transfers, intelligence sharing, and the use of bases, air space, waterways, and territory. Their most important dimensions fall into three categories: (1) basic purpose and function; (2) internal politics; and (3) external affects.

BASIC PURPOSES AND FUNCTIONS

The primary function of an alliance is to combine military strength against adversaries. The combined strength may be used in various ways to advance collective and individual purposes. It is most often used for deterrence, to signal to potential aggressors that they will meet such combined resistance that aggression will not pay. But it may also be used more offensively to compel others into political submission. Both of these coercive strategies, nevertheless, hinge on the most basic alliance function, to promote cooperative war fighting, for that is what makes them credible.

Although the process is never frictionless, alliances tend to form and deform in response to shifting concentrations of power and the threats they pose. Because threats are a function of intentions as well as power, compatibility of national aims tends to drive alliance patterns. Alliances may also form along lines of ideological or religious affinity, because the shared values are likely to be endangered by common threats. In late-nineteenth-century Europe, for example, a conservative alliance based on monarchical solidarity—the Three Emperors League of Prussia, Russia, and Austria-Hungary—formed against the spread of radicalism at home and abroad. Thus the political logic of combining strength against a common threat holds, even when the calculus is not determined by external power configurations alone.
Alliances

When alliances fight in general wars the common interests they stand for tend to reflect status quo or revisionist goals. The former seek to uphold the prevailing territorial divisions and political frameworks of an international system. The latter seek to overthrow them. At the start of World War II, the revisionist alliance (or “Axis”) of Germany, Italy, and Japan joined in rejecting the League of Nations, and in pursuing territorial conquests and a new international economy. It was opposed by a status quo alliance composed of Britain and France, and their allies in Eastern Europe.

But allies’ purposes are often more complicated than such broad generalities suggest, for partners will also seek parochial and perhaps contradictory aims, including control over each other. Once the Soviet Union and the United States joined Britain in World War II, their Grand Alliance sought not only to eliminate enemy regimes in Rome, Berlin, and Tokyo, but also to preserve fading empires, extend new spheres of influence over satellites, and create the United Nations and a multilateral liberal economic system. There were obvious tensions among these goals, and they were amply manifest in the international politics of the cold war.

INTERNAL POLITICS

Alliances require material and/or political sacrifices. They can also multiply dangers by provoking counter-alliances and new threats. Allies will thus struggle over the distribution of the costs and benefits of their enterprise, each trying to shift obligations and dangers onto the others. Two basic organizational features shape these internal politics: the number and relative strength of the allies. Increasing the number of allies makes it harder to reconcile disparate priorities. Equality of power among allies adds to the trouble by making it harder to determine whose contributions and priorities must trump. In bilateral alliances, the internal politics are less complicated between strong and weak partners, and more complicated between roughly equal ones. In multilateral alliances of unequal partners the internal politics are yet more difficult, and most difficult of all are multilateral pacts of equals. Regardless of what form an alliance takes, each partner will try to avoid two elementary risks: The first is being abandoned by one’s allies at a moment of grave danger; the second is being entrapped in a fight for an ally’s parochial interest that harms one’s own. These twin risks pose an inherent dilemma of alliance politics, and especially during periods of international crisis, much of alliance politics reflects the strivings of each ally to navigate through it.

Although it creates the danger of entrapment, forging an alliance in peacetime is advantageous because it allows allies to send diplomatic signals and coordinate military plans and forces in ways that increase deterrence and the prospects for military victory. In principle, the more deeply allies coordinate and integrate national strategies, forces, and operations the more effective and beneficial the alliance will be. Yet even when allies agree strongly about their common political purposes, and share a high degree of trust, the business of coordinating let alone integrating military strategies, postures, and operations, can be deeply divisive—within governments as much as between them. Traditional wisdom holds that divisions will recede as common dangers increase, and grow as common dangers fade. Thus wartime alliances tend to unravel after victory, as the Anglo-American–Soviet alliance did after World War II. However, the cleverest and most menacing adversaries will incite and exploit divisions within opposing alliances; then even great danger will not mute debilitating internal politics.

Important questions in IR concern the conditions for taming corrosive alliance politics. Shared norms and transparent decision-making may help liberal democracies to make and keep stronger alliance commitments. Institutionalized alliances, possessing routine processes for political decision-making and military coordination, supported by deliberative bodies and bureaucracies, may also be more robust. Such institutionalization, especially in an alliance of democracies, may even be transforming, creating an unusually cohesive security community in which partners tend to interpret and react to world politics in increasingly convergent ways. The North Atlantic Treaty Organization (NATO)—the most institutionalized and democratic alliance in history—may for this reason have continued to function and adapt long after its main opponent, the Soviet-led Warsaw Pact, crumbled.

EXTERNAL EFFECTS

Alliances are a primary means for balancing power in international politics. Most dramatically this occurs when broad alliances form against an aggressor, like Napoleonic France, that threatens to suborn the international system. Short of such extremes, alliances may foster international order and stability by spreading deterrence and predictability among states and a sense of assurance and restraint within them. But alliances have often been seen as causing more not less international warfare. First, because competitions in alliance building can create spirals of insecurity that make war more likely. Second, because once small local wars start, alliances may widen them and make them more destructive through webs of commitments on each side. That pathology is most associated with the start of World War I in 1914 when two tight alliances, with France and Russia on one side, and Germany and Austria-Hungary on the other, became deadlocked during a crisis between Austria-Hungary and Serbia. Though both were conceived as defensive alli-
Alliances to prevent war, they seem to have dragged the European powers, and much of the rest of the world, into catastrophe.

The idea that alliances promote peace and stability was boosted by NATO’s cold war successes in deterring a Soviet-led Warsaw Pact attack on Western Europe, and fostering cooperation within the alliance between historical enemies West Germany and France. Expectations about reproducing the latter effect motivated NATO expansion after the cold war, when former Warsaw Pact members in Eastern Europe were left in a region of strategic uncertainty without alliance safeguards. NATO’s members overcame internal disputes over the scope and pace of enlargement, and agreed to expand the alliance eastward to project stability and promote democracy within the new member states. This logic for projecting security through alliance growth thus evoked the idea that democratic alliances can instill deep bonds of common identity and security community.

In the first decade of the twenty-first century, the strongest case for such bonding remained the Anglo-American alliance: forged in world wars, it was deepened and institutionalized bilaterally and multilaterally through NATO during decades of cold war. As their security concerns shifted to nuclear proliferation and transnational terrorism, those two allies showed surprising cohesion in fighting wars in Iraq and Afghanistan. With other NATO members, however, especially concerning Iraq, there was greater political acrimony and less evident commitment to joint effort, showing that even the deeply democratic and institutionalized transatlantic security community remains vulnerable to divisive and perhaps debilitating internal politics.

As the century unfolds, two issues concerning alliances will loom largest for students and practitioners of international relations. The first is the extent to which traditional alliance frameworks can be retooled and mobilized to redress amorphous transnational terrorist threats that are less amenable to solutions based on combined military strength. The second is the extent to which traditional alliance frameworks will come into play against the largest and fastest-growing powers. Will new alliances form and tighten in reaction to preponderant American military power? Will alliances in Asia and the Pacific endure and grow—or wither and fracture—as China’s military posture and prestige climbs? The broad contours of twenty-first-century international politics will be defined by answers to these questions.

BIBLIOGRAPHY
In 1954 Allport published his second classic work: *The Nature of Prejudice*. It too shaped its field for half a century. This book departed from previous conceptions of prejudice and advanced an array of new insights later supported by research. Two theoretical stances proved especially important. Allport held that intergroup contact under favorable conditions could substantially reduce prejudice and offer a major means of improving intergroup relations. Research throughout the world, as well as such events as the ending of apartheid in South Africa, support the theory. Allport also countered the then-fashionable assumption that group stereotypes were simply the aberrant cognitive distortions of prejudiced personalities. Advancing the view now universally accepted, Allport insisted that the cognitive components of prejudice were natural extensions of normal processes. Stereotypes and prejudice, he concluded, were not aberrant but all too human.

Though known principally as a theorist, Allport also had an active empirical career. In his efforts to forge a broad psychology, he employed a range of methods—from the study of personal documents to nomothetic tests and ingenious experiments. His most famous test measured basic values. His influential experiments opened up research on eidetic imagery, expressive movement, radio effects, and rumor.

Critics of Allport’s personality theory regard it as too static and overly oriented to the sane and mature. Social science critics regard Allport’s work as too individualistic and detached from social factors. Nonetheless, he remains one of the most cited writers in the social psychological literature.

Allport’s lasting influence is based on three interwoven features that characterize all his work (Pettigrew 1999). First, he offered a broadly eclectic balance of the many sides of psychology. Second, he repeatedly formulated the discipline’s central problems and proposed innovative approaches to them. Typically, his suggested solutions were loosely sketched out and not readily accepted. Years later, however, his ideas often gained acceptance and were expanded with new concepts. Finally, Allport’s entire body of scholarly work presents a consistent and seamless perspective both forcefully advanced and elegantly written.

ALMOND, GABRIEL A.
1911–2002

Gabriel A. Almond was one of the most creative political scientists of the latter half of the twentieth century. He carried out major work on public opinion and foreign policy; he did pioneering work on political culture, making the study of the subject much more systematic; he was the leading figure in the field of comparative politics, in which he broke down the single-country focus and made the field truly comparative; he brought sophisticated psychological analysis into the study of politics; and he ended his long career with significant work on religious fundamentalism.

*The American People and Foreign Policy*, published in 1950, was one of the earliest works in behavioral political science. Almond used survey data to explain the periodic swings of American public opinion toward international affairs—from idealistic to cynical attitudes, from a support for withdrawal to support for intervention, and from optimism to pessimism. In *The Appeals of Communism*, published in 1954, he used surveys and in-depth interviews to demonstrate the fundamentally different nature of the appeals of the communists in countries where it was the “normal” ideology of the working class and in countries where it was a less class-based manifestation of alienation.

Almond’s most lasting contribution was to the systematic study of comparative politics. *The Civic Culture* (1963, coauthored with Sidney Verba) was one of the first large-scale cross-national survey studies. With its examination of the cultural roots of democracy in five nations, it opened the new field of comparative surveys and was one of the first attempts to study cultural factors in comparative politics systematically. In *The Politics of the Developing Areas*, Almond and James S. Coleman proposed a broad analytical framework for identifying the basic institutions and processes of social change. In *Crisis, Choice, and Change*, Almond and his collaborators considered the role of leadership and strategic choice in political change.

Almond also contributed analyses of the state of political science. In *A Discipline Divided*, he called for a political science that was open to many approaches, a political science that was empirical and whose conclusions were open to testing and falsification.

Late in life, Almond led a large-scale project on fundamentalisms sponsored by the American Academy of Arts and Sciences. The project culminated in an overview volume, *Strong Religions*, authored by Almond, R. Scott Appleby, and Emmanuel Sivan. The authors consider the role of fundamental religion most broadly, from its social roots to its political consequences. They do not simplify and reduce all forms to a single pattern, but instead allow one to see beyond the particularities of each of the forms of fundamentalism.

ALPHA FEMALE

SEE Alpha-male.
ALPHA-MALE
In 1802 P. Huber related the concept of dominance to the social behavior of bumblebees. Almost 100 years later, Thorleif Schjelderup-Ebbe (1935) wrote about “pecking orders” in chickens, describing a hierarchy in which the top-ranking chicken could peck all the others with impunity and the second-ranking could do the same thing to all except the first one, down to the last-ranking bird, which was pecked by all and could peck none in return. The idea of dominance was applied to explain the directionality of aggressive behavior in animals that live socially and was defined as a relationship learned through previous experience.

DOMINANCE IN NONHUMAN PRIMATES
Ray Carpenter applied the concept to nonhuman primates and considered it a universal principle that shapes all primate social organizations (1954). Interest quickly was focused on individual attributes that might account for the achievement of high rank and its consequences. Size and strength may contribute, but Masao Kawai and Syunzo Kawamura (1958) and Bernard Chapais (1992) demonstrated that social skills and alliances are far more important in determining the dominance positions of monkeys. Irwin Bernstein and colleagues showed that dominance ranks have meaning only in a specific social context (1980). In different groups individual ranks can be reversed, and the highest-ranking individual in one group can be the lowest-ranking in another. Dominance thus is not an attribute that can be studied in an isolated individual.

The functions of dominance were speculated to relate to instrumental aggression, a process in which aggression is used to gain something at the expense of a rival. Dominant individuals were expected to have priority of access to food, mates, and other resources. However, the existence of mixed evolutionarily stable strategies was interpreted to mean that alternative means might obscure the expected correlation between rank and resources. If dominance meant access to incentives, it was speculated that individuals would strive actively for high rank, but William Mason and Sally Mendoza found little evidence that primates fight specifically to attain rank (1993). Moreover, empirical studies of genetic fitness and high rank have not always demonstrated the expected correlation. Market theories that suggest that animals should perform “favors” for those of high rank in exchange for “services” such as agonistic aid and tolerance also have received mixed support. Although there are good correlations between grooming and dominance in some groups, the tendency for kin or other close associates to both groom and aid one another can override any tendency for lower-ranking animals to groom higher-ranking animals.

BIOLOGICAL CORRELATES AND BEHAVIOR
The search for biological correlates of dominance rank revealed that whereas some characteristics may contribute to the attainment of high rank, others may follow as a consequence of achieving that rank. Robert Rose and colleagues initially assumed that the correlation between male testosterone levels and dominance suggests that hormones contribute to dominance (1971) but later found that recent histories of winning or losing a fight account for profound changes in testosterone levels. The correlation with dominance pertained only immediately after fighting had established or changed dominance positions. Robert M. Sapolsky reported that cortisol levels were lower in dominant individuals, but only when the group was in a period of social stability (1984). Hormone levels both influence social interactions and are a result of those interactions.

Since dominance relationships are often linear, the first position is called alpha and the last is called omega. The alpha animal can be expected to be the “leader” of a primate group, but high agonistic rank does not lead routinely to leadership of group movements or other activities. The alpha individual may be assumed to be integral to the defense of the group against external and internal threats, but the “control role” often is played by individuals other than the alpha. In macaque and baboon societies sexual dimorphism in body size, canine size, and other features may contribute to a male becoming the alpha animal in the group, but sometimes a female may outrank all the males. Among the lemurs females routinely assume the alpha position. Nonetheless, with the original assumption that males would be the highest-ranking individuals, investigators asked whether females also have an “alpha” with special characteristics, as is assumed for alpha males. Of course this required separating the sexes in determining relative ranks, and some researchers went so far as to suggest that all adult males outrank all adult females. Whereas this occasionally may be true for some species, it is far from a general rule.

The focus on biological correlates of “alphanness” led to considerations of the evolutionary consequences of natural selection on behavior. If males were selected on the basis of their ability to defeat other males to obtain access to females (Charles Darwin’s intrasexual selection), larger, more aggressive males would have higher genetic fitness. Aggression was expected in males, whereas females were expected to be more passive and even “coy,” inciting males to demonstrate their superior prowess. Male aggression also could be directed against females to coerce mating.
Alpha-male

(reducing the effect of Darwin’s second principle of sexual selection: epigamic selection, or “female choice”). With a long history of natural selection favoring aggressive males that fought other males and coerced females, one would expect strong differences in the aggressiveness of the sexes, and such differences were assumed and supported by the more extreme consequences of male aggression. This, however, is a poor indicator of differential initiation, participation, and duration of aggression. Because of different anatomic capabilities, aggression by females may take forms different from those of male aggression and inflict less damage, but does this mean that verbal aggression or social ostracism (presumed to be more common in human females) is any less aggressive than physical attacks? In many species the frequency and duration of female aggression exceed those of males, although the consequences of male aggression are usually more severe.

If, however, evolution has favored males that are highly aggressive and engage in sexual coercion, it is not surprising that males, with their correlated higher levels of male hormones, are more aggressive than females. (The relationship with male testosterone is widely assumed and castration often is recommended to reduce aggression in animals and human males, but there is little proof that there is a direct correlation between testosterone levels and aggression.) If male aggression is “natural,” Richard Wrangham and Dale Peterson argued in 1996, males are possessed by “demons” that drive their behavior. They fight and copulate at every opportunity because evolution has shaped them to do that. If natural selection is responsible, should they be blamed, or should researchers be more accepting of male aggression and sexual coercion? Does this excuse the inexcusable? Are people really programmed by their “hormones” and heredity so that “free will” has little influence on “typical” sex behavior? Is sexual dimorphism proof that males have greater physical fighting abilities so that they can defeat other males in contests for mating, or is it possible that other factors promote a sexual division of labor that favors larger size and fighting ability in males and/or smaller size in females? Sexual dimorphism could as easily be due to differences in the social roles of males and females with regard to group defense against predators, rival groups, or other sources of potential disturbance or even to differences in foraging patterns that reduce competition for food within a group. Plausibility seems the only argument for favoring one interpretation over another, and sexual dimorphism often is assumed to be proof of male mating patterns.

THE HUMAN ALPHA

The application of speculations about nonhuman primate behavior to the understanding of the human condition is fraught with peril. “Alphaness” is more an artifact of people’s ability to count than a matter of biology. Linear hierarchies are appealing, but the game paper, scissors, rock also can describe dominance. Researchers see an entire group, but animals may be more self-centered and see only their individual relationships with the members of the group. They may not have abstract concepts of group organization.

Dominance in human groups may be pronounced in institutions with a rank hierarchy such as the military; an alpha may be suggested when groups have a clear leader and the others are all more or less equal followers, but some human groupings do not show structures that suggest that individuals have histories of coercive relationships that lead to recognized superiors. Christopher Boehm suggested that many human social structures have specific mechanisms that preclude the development of alpha positions (1994). The existence of leadership does not require aggression or a history of aggressive contests, although that may occur in some circumstances. Superior reproductive success can correlate with high social status, but it need not. (Genetic fitness is defined by the number of replicates of an individual’s genes that show up in a future generation compared to the average individual in the population—roughly equivalent to the number of grandchildren or great grandchildren that one has. For the last several decades there has been an inverse relationship between economic status and genetic fitness.) Presumed correlates of dominance or alpha status cannot be construed as evidence that alpha status exists.

If the term alpha-male is used to indicate a male that uses social position to obtain more mating or power over others, surely females might do the same and there would be alpha females. These concepts are a far cry from the origins of the term in animal behavior, where alpha was used to designate the individual that could aggress against others without fear of retaliation. Whether dominance leads to increased mating or access to resources is an empirical question, and the data do not always support such hypotheses. Thus, the relationships among dominance rank, genetic fitness, and status are empirical questions with regard to humans as well, and one cannot assume that success in any one area implies success in the others. Researchers may describe alpha individuals of either sex or a group, but they should describe data and not assume data on the basis of theory.

Irwin S. Bernstein
AL-QAEDA

Al-Qaeda, an Arabic word meaning “base,” is an international Islamic terrorist group led by Osama bin Laden, who founded Al-Qaeda along with Abdullah Azzam (1941–1989) in Afghanistan in 1988 (9-11 Commission Report, p. 56). Al-Qaeda’s administrative and recruitment foundation sprang from the associations of Muslim warriors (mujahideen) that had formed in the early 1980s to fight the Soviet invaders in Afghanistan. These fighters later became the backbone of Al-Qaeda’s forces.

After the Soviet retreat from Afghanistan in February 1989, bin Laden returned to his native Saudi Arabia. When Iraq invaded Kuwait on August 2, 1990, bin Laden offered to raise a volunteer Islamic army to fight Iraq. The Saudi government refused, preferring to seek help from the United Nations. During the ensuing war, bin Laden opposed American involvement, calling the United States an “enemy invader.” Following his disagreement with the Saudi regime, bin Laden and his supporters went to Sudan in 1991 (9-11 Commission Report, p. 57). International pressure on the Sudanese government later obliged bin Laden to return to Afghanistan in 1996, where he and his supporters remained until the Taliban government was defeated following the invasion of the American-led coalition forces in 2001.

Since 1991 Al-Qaeda has launched several attacks on various Western targets: suicide car bombings of the American embassies in Nairobi, Kenya, and Dar es Salaam, Tanzania, on August 7, 1998; the suicide attack on the USS Cole in the port of Aden in Yemen on October 12, 2000; the September 11 attacks on the Pentagon and the World Trade Center in the United States in 2001; and the suicide attack in Riyadh, Saudi Arabia, on May 12, 2003. When American-led coalition forces invaded Iraq on March 20, 2003, Al-Qaeda–linked groups swung into action. On October 21, 2004, they united as “Al-Qaeda in Iraq” under the leadership of Abu Musab al-Zarqawi, a Jordanian who was killed by American forces on June 7, 2006.

Al-Qaeda and its ideology were established on a background of the decline of socialism and communism in the face of Western culture and capitalism and increasing Islamic influence. Al-Qaeda was influenced mainly by the extreme ideologies of the Salafi stream of Islam, particularly those of Sayyid Qutb (1906–1966), an Egyptian religious theoretician. Qutb viewed the West and its culture as the greatest threat to Islam and advocated the establishment of an Islamic state based on Muslim religious law. This idea became associated with bin Laden’s contention that Westerners violate the honor of Muslims, humiliate them, and try to possess their lands. Muslims must therefore fight against the West in a jihad holy war. The concept that best represents Al-Qaeda’s ideology is that of “defensive jihad,” according to which it is every Muslim’s religious obligation to fight the attackers, seen as the Western countries headed by the United States.

This ideology molded Al-Qaeda’s goals, which are: (1) to establish Islamic regimes like the Taliban, based on Islamic religious law, in all the Arab states; (2) to free all Islamic lands from any Western presence or influence; and (3) to establish the “pious caliphate” (a pan-Arabic Islamic kingdom) over all the Muslim lands. These goals were expressed in bin Laden’s fatwa (religious legal proclamation) of February 23, 1998, although he himself has no religious authority. In the fatwa, bin Laden asserted that the United States, through its policies in Muslim lands, had declared war on God, his Messenger, and all Muslims.

Al-Qaeda is one of the few terrorist groups structured with a distinct separation between the majlis a-shura (the core leadership) and the action groups. This structural difference makes it easier for Al-Qaeda to function without a home country as a base that provides it with political and military sponsorship and hosts its training camps and administrative headquarters. As a result, cells of activists have become semi-independent centers of activity. Each cell is composed of a few members, some natives of their locale, all ready to die for their cause when the leadership so orders. Al-Qaeda cells are scattered throughout the world, with a conspicuous presence in Europe, and often have only Internet connections with the leadership.

ALTHUSSER, LOUIS

1918–1990

Born in Algeria, the troubled and reclusive French philosopher Louis Althusser revolutionized Marxist phi-
loosophy with his radical theses on Karl Marx’s oeuvre and influenced several generations of students at the École Normale Supérieure, including Michel Foucault, Étienne Balibar, Jacques Ranciere, and Régis Debray. Many of Althusser’s arguments, often theoretical interventions in French Communist Party (of which he was a member) and international Left debates, were published in socialist journals or articulated in public lectures and seminars (and subsequently compiled as volumes) in keeping with his determination to “intervene as much in politics as in philosophy, alone against the world” (Althusser 1993, p. 173).

Arguing that socialism was scientific and humanism ideological, Althusser challenged Hegelian and humanistic readings of Marx’s work as a coherent whole, by marking an “epistemological rupture” between Marx’s early (pre-1845), humanistic writings and his subsequent “mature,” “scientific” works such as Reading Capital. The problématique (theoretical framework that encapsulates both presence and absence of concepts) of Marx’s mature work was described as historical materialism, a “science of history” that provided a revolutionary conceptualization of social formation and change. This “History Continent” discovered by Marx, was original and unprecedented and “induced” the birth of a new, “theoretically and practically revolutionary philosophy”—dialectical materialism—distinct from historical materialism (1970a, p. 14).

Althusser’s “symptomatic” reading performed the dual function of revealing the “unconscious” of Marx’s texts and illuminating their underlying deep structures, while demonstrating the methodology mobilized by Marx himself in reading classical political economy. Contrary to the prevalent economically deterministic readings of Capital, Althusser identified a wider range of pratique (processes of production or transformation) that constituted a social whole or “structure in dominance” that had no essence or center. Each economic, political, ideological structure “existed in its effects,” and was asymmetrically related but autonomous, the economic determining “in the last instance” which element was to be dominant. This dominance was not fixed but varied according to the “overdetermination” of the contradictions in social formation and their uneven development (1970b, p. 188).

While Althusser was influenced by his teachers such as Maurice Merleau-Ponty and Georges Canguilhem, his indebtedness to psychoanalysis was profound and particularly evident in his expositions on ideology. He distinguished between ideology (eternal, omni-historical and structural, like Freud’s notion of the unconscious) and ideologies (particular, sociohistorical). Ideology is a “representation of the imaginary relationship of individuals to their lived conditions” and has a material existence in practices and apparatuses. Of these, Ideological State Apparatuses (ISAs) such as religion, schools, and family are significant as they interpellate or “hail” subjects to accept their role within the system of production relations by “misrecognizing” their subjecthood as agency. Thus, an individual is simultaneously subject (of) and subject (to) ideology (1971, pp. 160–170).

Althusser consistently refuted accusations that his omni-historical, structuralist formulations disenabled revolutionary practice by insisting that he was never a structuralist but rather a Spinozist; structuralism was an accidental by-product of his antihumanist, theoreticist deviation via Spinoza’s notion of structural causality. Further, his Marxism could never be structuralism because it affirmed the primacy of class struggle and thus “rests on revolutionary class theoretical positions” (1976, p. 130).

Althusser battled unbearable sadness and mental instability for much of his adult life. Althusser’s murder of his wife, Helene Rytman, with whom he shared an extremely intense emotional and intellectual relationship, and his subsequent efforts to “answer charges” in his memoirs, The Future Lasts Forever (1993), are respectively horrific and poignant examples of the fragile balance between madness and reason upon which he constantly teetered while nevertheless always being aware of the powerful role that violent organizations had played in his life.

ALTRUISM

One fundamental question about human nature is whether people are ever capable of genuinely altruistic acts. The term altruism is typically used to reflect one of two concepts. The first is evolutionary altruism, which refers to helping behavior that benefits another at some
cost to oneself. Evolutionary altruism reflects behavior caused by many different habits and motives assumed to have evolved in a species because they promote the long-term reproduction of species members’ genes. The term altruism is also used to reflect psychological altruism, which refers to a motivational state with the goal of increasing another’s welfare. Psychological altruism is typically contrasted with psychological egoism, which refers to a motivational state with the goal of increasing one’s own welfare.

There has been much debate about whether humans possess the capacity for psychological altruism. One claim that assumes psychological altruism exists is the empathy-altruism hypothesis, which states that feelings of empathic concern for a person in need evoke an altruistic motive. Feelings of empathic concern have been contrasted with feelings of personal distress. Feelings of personal distress are assumed to evoke motivation to reduce these unpleasant emotions by either escaping continued exposure to the person’s suffering or by helping, whichever happens to be the least costly option in the situation. Consistent with these claims, research suggests that people feeling empathic concern tend to help even if they can easily escape exposure to the victim’s suffering, whereas people feeling personal distress tend to help only when escape from continued exposure to the person’s suffering is difficult or impossible.

The tendency for an observer to help a needy other as a result of evolutionary altruistic or psychological altruistic processes is also influenced by factors that affect helping behavior more generally. For example, research demonstrates that observers are more likely to help a person if they (1) notice the person and (2) recognize that the person is in need. Even then, help is likely only if observers (3) assume personal responsibility for reducing the person’s need. Research also suggests that the number of observers witnessing the need situation can actually reduce the likelihood that any one observer will offer help (i.e., the bystander effect). However, observers who experience psychological altruism may be immune to this diffusion of responsibility because empathy may promote feelings of responsibility for the victim regardless of the number of additional bystanders present in the situation.

In development, helping behavior appears to emerge as early as two years of age in humans. However, the cause of these behaviors (e.g., evolutionary altruistic versus psychological altruistic processes, or neither) has been debated. There is also debate about the extent to which evolutionary altruistic or psychological altruistic processes influence, or are influenced by, an individual’s personality characteristics. Some research shows that people scoring high on personality measures that assess altruism-relevant characteristics (e.g., perspective-taking, emotionality, and responsibility for others’ welfare) are more likely to help than people scoring low on these measures. Again, it is unclear whether such behavior reflects evolutionary altruistic processes, psychological altruistic processes, or neither. Future research will almost certainly address, and hopefully answer, these and other questions about the existence of altruism in humans.

ALTRUISM AND PROSOCIAL BEHAVIOR

Social scientists use the word altruism to describe two distinct phenomena—motivation and prosocial behavior. Although it is more common to describe altruism as a motivational state with the goal of increasing another’s welfare, some researchers, especially within the field of sociobiology, use the term as a synonym for prosocial behavior, which refers to any behavior that benefits someone other than oneself, regardless of the motivation involved. The factors that predict when, and for whom, prosocial behavior will occur can be divided into three categories—dispositional, situational, and evolutionary.

Dispositional factors are personal characteristics that predispose an individual to engage in prosocial behavior. These include sensitivity to norms of personal and social responsibility, internalization of prosocial values, moral reasoning ability, a tendency to empathize, intelligence, nurturance, religiosity, and self-esteem. Although none of these factors alone predicts prosocial behavior well, a combination of empathic tendencies, moral reasoning ability, and sensitivity to norms of personal and social responsibility constitute what some have called an altruistic personality. A person may also be prone to engage in prosocial behavior as a consequence of social learning. Those who have received (or observed others receive) rewards for helping, or punishments for not helping, are more likely to help than are those who have not.

Situational factors are stimuli in an individual’s environment that promote prosocial behavior. There are many
situational factors that affect prosocial behavior, but only a few have received detailed scientific attention. Among these is the presence of bystanders. In an emergency situation, as the number of bystanders increases diffusion of responsibility for helping also increases, which, in turn, reduces the likelihood of prosocial behavior. Another factor is the presence of prosocial norms, which are written and unwritten rules of behavior that communicate when, how, and for the benefit of whom help is to be provided. If a situation promotes attention to prosocial norms, then prosocial behavior is more likely to occur. Information about the cause of a victim's need also affects prosocial behavior such that those viewed as not responsible for their need are more likely to be helped. Factors that increase positive mood and feelings of empathy promote prosocial behavior, as do situations that promote negative mood or personal distress, but only if prosocial behavior is perceived as rewarding or if escape from such feelings is possible only through helping.

Evolutionary factors are those that promote prosocial behavior as a consequence of natural selection. According to sociobiologists, individuals are predisposed to benefit those who are likely to share or promote their own genes. *Kin selection* suggests that people are more likely to benefit genetically related individuals because helping kin can promote the survival and reproduction of one's own genes in future generations. Similarly, *reciprocal altruism* suggests that people will help those who are likely to help them back because doing so increases the likelihood that one's own genes will be protected or promoted when in need at a later date. Research also suggests that younger individuals are more likely to receive aid (suggesting an evolved sensitivity to those displaying characteristics typical of offspring) unless essential resources are scarce, in which case only those capable of reproduction are likely to be helped.

**ALZHEIMER’S DISEASE**

Alzheimer’s disease (AD) constitutes about two-thirds of all dementia cases. Dementia is defined as cognitive impairment of sufficient severity to interfere with daily functioning. AD currently affects twelve million people worldwide, including over four million in the United States. These numbers could triple by 2050 due to increasing life expectancies. The prevalence of AD is approximately 1 percent among those under 70 years and increases with age to about 40 percent in those 85 years and older. It is the fourth-leading cause of death in the United States among persons older than 65 years. The term sensitivity was used in the past to indicate severe age-related cognitive changes. It is now recognized that subtle cognitive changes do occur with aging, but very marked changes are unexpected unless there is an underlying disease process. The recognition of AD as a disease syndrome has transformed cognitive impairment from an expected stage of life to a medical problem, prompting public concern, new policies, and advocacy.

AD is characterized by a subtle onset and gradual decline. The most prominent early symptom is memory impairment, particularly the ability to remember recent events or names of familiar people or objects. This is accompanied by other, initially subtle, cognitive deficits, such as impaired verbal, spatial, or problem-solving skills. Other symptoms may include disorientation, increased irritability, mood lability, depression, anxiety, and sleep disturbance. Delusions are common, as are behavior problems (e.g., aggression, wandering, disregard for normative social conduct). As the disease progresses, basic activities of daily living, such as eating and dressing, become impaired. Late-stage AD is marked by the loss of recognizable speech and the inability to control bodily functions, leaving patients completely dependent on caregivers. Death occurs approximately eight to ten years after diagnosis (range three to twenty years).

The causes of AD are currently not fully understood. The most evident brain abnormalities are neuritic plaques (clumps of beta amyloid protein) and neurofibrillary tangles (Tau protein strands). Soluble forms of these abnormalities may be toxic to the brain. There is also a deficiency in the neurotransmitter acetylcholine, clogging of the NMDA-glutamate receptor, and considerable brain atrophy (shrinkage).

AD can be familial (inherited) or sporadic. Familial AD is rare and begins earlier in life (age 30 to 60 years). There are at least three genes that can cause familial AD: presenilin 1, presenilin 2, or the amyloid precursor protein gene. Sporadic AD typically occurs after age 65 and accounts for 90 percent of all AD cases. The primary risk factor for sporadic AD is age. Others include a family history of AD, carrying the E4 allele (variant) of the
apolipoprotein E (ApoE) gene, being female, Down syndrome, head injury, a prolonged loss of consciousness, diabetes, and cardiovascular disease. Compared to Americans of European descent, African and Hispanic Americans are at greater risk for AD, whereas Asians and Native Americans are at lower risk. It is unclear whether these differences are due to genetic heritage, health, or social or cultural differences between ethnic groups. Protective factors include higher occupational attainment, education, literacy, physical exercise, and engagement in socially and intellectually stimulating leisure activities.

Current drug treatments of AD consist of cholinesterase inhibitors, which increase the neurotransmitter acetylcholine, and NMDA receptor antagonists, which block glutamate from activating NMDA receptors. There is some evidence that antioxidants (vitamins E), anti-inflammatory agents (ibuprofen, aspirin), and estrogen may slow the progression of AD. All current treatments are symptomatic and only marginally helpful. There is weak support for the effectiveness of cognitive interventions in improving cognitive and emotional health during early AD.

The burden of AD is enormous, both to society and to individual caregivers, who suffer from financial and emotional distress. Lack of effective treatment, high health care costs, and increasing numbers of patients make AD one of the most challenging medical conditions.

**AMBEDKAR, B. R.**

1891–1956

Bhimrao Ramji Ambedkar contributed to the development of the Indian nation during the formative stages of its history in the first half of the twentieth century. Ambedkar was born into a low-caste untouchable family in Maharashtra state in western India. Because his father had been in the military service through a limited open-
he organized the Indian Buddhist Council to help spread Buddhism.

**SOCIAL ANALYST AND POLICYMAKER**

Ambedkar was a scholar as well as a man of action. His aim was to use insights from various studies on Indian history and society to restructure Indian society on the principles of equality, liberty, and fraternity. He had differences both with contemporaries like Mahatma Gandhi (1869–1948) and with India’s leftists. In Ambedkar’s view, the problem of the untouchables was rooted in the caste system, which was based on the principle of inequality, isolation, and exclusion, with an ideological support from Brahmanic-Hindu religious philosophy. Gandhi, in contrast, believed that the institution of untouchability had no base in Hinduism and treated it as an aberration. The leftists, on the other hand, believed that the caste system had economic foundation and could be resolved through industrialization and a move toward socialism. Solutions differed correspondingly. Gandhi emphasized moral solutions and a change of heart among Hindus. Marxists advocated economic equality for the annihilation of caste discrimination. Ambedkar, however, favored dismantling both the religious-ideological and economic foundations of the caste system. At the social-religious level, he argued for the acceptance of the egalitarian Buddhist religious tradition in Indian society. Economically, he favored a strong state, a democratic socialism oriented to rapid economic development, and a system of compensatory affirmative action policy that included “reservations” in legislature, public services and educational institutions to ensure equal access to economic opportunities. As a minister for energy and irrigation under the last British government, Ambedkar played a major role in initiating economic planning in India.

Ambedkar turned toward Buddhism and converted with a large number of followers in 1956. Buddhism, in his view, was a harbinger of economic and social/cultural egalitarianism and political democracy. This perspective on the problems of Indian society had an immense impact on the issue of reform in Hindu society.

Ambedkar also had a profound impact on the development of policies opposing discrimination and facilitating the empowerment of discriminated groups. Because Hindu society is exclusionary and discriminatory in character, it requires policies of social inclusion. The set of measures aimed at ending discrimination and increasing equal opportunity and economic empowerment included equal rights legislation, legal safeguards against discrimination, and affirmative action to ensure fair participation to the discriminated and excluded groups of untouchables. Legal safeguards against discrimination came with the Anti-Untouchability Act of 1955, and affirmative action came with the Reservation Policy for representation in legislatures, educational institutions, and public jobs, measures that were instituted in 1935 and were finally incorporated into the constitution of India in 1950. In support of economic empowerment, Ambedkar favored a particular type of socialistic economic framework, which in his view would ensure economic equality to poor and marginalized groups. Ambedkar’s contribution is, thus, valuable both in social thought and in the shaping of policies against discrimination. As chairman of the drafting committee of the Indian constitution, he helped to create the basic political, economic, and social framework under which Indians live today.

Ambedkar died in 1956, and the Indian state recognized his unique contributions. He was posthumously awarded the country’s highest civilian honor, the Bharat Ratna (Jewel of India) on April 14, 1990.

AMERICAN ANTHROPOLOGICAL ASSOCIATION

The establishment of the American Anthropological Association (AAA) in 1902 was the culmination of a gradual process of professionalization in American anthropology that revealed subdisciplinary, regional, and theoretical tensions within the emerging discipline. The first anthropological society in the United States was the American Ethnological Society, founded in New York by Albert Gallatin (1761–1849) in 1842 and revived by Franz Boas (1858–1942) in the 1890s to balance the Washington-based Bureau of American Ethnology’s potential stranglehold that threatened to dominate anthropology on a national scale. Section H of the American Association for the Advancement of Science, established in 1882, already provided annual meetings for anthropologists but not visibility among the social science disciplines or discrete professional identity.

Abortive efforts to establish a separate organization in 1897 floundered over Washington hegemony, with the compromising being a new series of the Bureau of American Ethnology–based journal American Anthropologist co-organized by W. J. McGee (1853–1912) of the bureau and Boas in New York. The diverse editorial board reinforced the revamped journal’s claim to national representation and self-consciously built toward a formal professional organization in the near future. Boas wanted to wait until he had trained more professional anthropologists and solidified his organizational control over the discipline.

The American Anthropological Association that was established in 1902 compromised between Boas’s insistence on professional gatekeeping and McGee’s populism, a contrast reflecting their respective institutional frameworks of university and government. The Washington contingent, backed by Frederick Ward Putnam’s (1839–1915) archaeological bailiwick at Harvard’s Peabody Museum of American Archaeology and Ethnology, supported evolutionary theory in the mode of Lewis Henry Morgan (1818–1881), whereas Boas critiqued this paradigm in favor of historical particularism.

Boas succeeded in restricting the organizational meeting to forty carefully chosen professionals, but McGee ensured that any interested person could join. The AAA began with 175 members, including sixteen women, incorporating members of the Anthropological Society of Washington. McGee became the first president, but his successors were carefully chosen to represent alternative regional and local components of the national membership. Boas served as the third president of the AAA in 1907 to 1908, succeeding Putnam, who had long been the permanent secretary of the American Association for the Advancement of Science. When the inclusive structure rapidly proved unwieldy, the establishment of an executive council further enshrined Boas’s aspirations to professionalism by limiting decision-making power to the established elite, increasingly under his patronage.

World War I (1914–1918) polarized the hyperpatriotism and racialism of the National Research Council against Boasian autonomy of science on both ethical and intellectual grounds. Boas was German and a pacifist about the war, a critic of eugenics, and ambivalent about collaboration between universities and museums. Archaeology and physical anthropology were left tacitly to Putnam at Harvard. In 1919, after the war had officially ended, Boas accused unnamed anthropological colleagues working in Mexico, representing his still powerful long-term nemeses in the Cambridge/Washington axis, of spying under cover of research. In the resulting furor, Boas was removed as anthropology’s representative to the National Research Council, censured by his own professional association, and removed from its council. Despite the apparent defeat, however, this was the last time that anti-Boasian forces would challenge successfully his organizational leadership, commitment to professional credentials, and effective critique of evolution, or that the institutional core of American anthropology would be academic. Thereafter, Boas’s former students and protégés edited the American Anthropologist, represented the AAA on the three research councils, and headed the growing number of university programs credentialing new anthropologists. The discipline and the AAA grew incrementally during the interwar years under this balanced structure.

During World War II (1939–1945), many anthropologists entered government service. At the war’s end, the discipline was poised for exponential growth. The 1945 annual meeting narrowly averted schism led by archaeol-
ogists and younger anthropologists. During the annual meeting of 1946, concurrent sessions were held for the first time. The 1946 AAA meeting introduced a distinction between members and fellows that persisted until the 1970s. The new structure maintained the inclusive subdisciplinary scope of cultural, physical, archaeological, and linguistic specialization (although the three latter also participated in independent associations). This structure was intended to render anthropology competitive among the social sciences. An AAA Research Committee was established to seek philanthropic support for anthropology in the transition to government funding and beyond. Increasingly, the competition would be interdisciplinary, seeking a place for anthropology among the social science disciplines.

The political upheavals of the 1960s initiated centrifugal as well as further numerical expansion in American anthropology. By the 1970s, the academic job market had contracted and many fledgling anthropologists found themselves working outside the ivory tower. Practicing anthropology emerged as the fifth subdiscipline in the AAA structure to accommodate this growing diversity within its membership. Increasingly, the most salient internal schism was a generational conflict between activism and objective science. Many anthropologists on both sides considered these mutually exclusive.

Under the presidency of Anthony F. C. Wallace in 1972, the AAA began its restructuring to mitigate the increasing size and cumbersomeness of the organization and to incorporate its ever more diverse versions of anthropology by establishing specialized sections, while retaining the overall organization as an umbrella. As the powerful university-based old guard was challenged by younger and more radical critics, the AAA strove to legitimize both the activists and the scientists within its membership. A new constitution in 1983 formalized this structure, producing over thirty sections and numerous interest groups and committees by the mid-1990s. Sociocultural anthropology dominated, as it had throughout the history of the AAA, but the other subdisciplines retained their affiliation with the umbrella organization.

Centripetal forces perhaps have come to the forefront again with the decision that AAA membership includes subscriptions to the American Anthropologist as well as section publications. Many AAA members belong to multiple sections and value this acknowledgement of the diversity within their profession. The organization is active in seeking a public voice for anthropology and anthropologists and in maintaining internal dialogue among anthropologists of diverse persuasions.

AMERICAN DILEMMA
Published in 1944, amid the massive destruction and racial genocide of World War II (1939–1945), An American Dilemma: The Negro Problem and Modern Democracy, by the Swedish economist and sociologist Gunnar Myrdal (1898–1987), not only challenged America’s democratic principles but also offered firm testimony to their promise. Myrdal’s epic study has framed racial discourse for more than half a century. Consistent with the times, Myrdal’s research team included some of the leading black intellectuals of the era—Ralph Bunche (1904–1971), Kenneth Clark (1914–2005), E. Franklin Frazier (1894–1962), Charles S. Johnson (1893–1956), and Ira Reid (1901–1968)—who were forced by custom
American Dilemma

and discrimination to work as his racial, if not intellectual, subordinates.

Myrdal saw the American race problem as a moral dilemma, concluding that legal segregation and the racial caste system were inconsistent with the American creed and its commitment to freedom, equality, and democracy. For Myrdal, one solution was located in the American system of education. Education represented a vehicle for combating racist beliefs as well as a way to improve black people's material conditions. Increased educational opportunities for blacks, and improved education about race for whites, he argued, represented an important step toward reducing racial prejudice, ending segregation, improving black economic development, and ultimately solving the puzzle of race in America.

THE AMERICAN DILEMMA AND ECONOMICS

In American Dilemma, Myrdal rightly described the economic situation and prospects of black Americans at the close of the Second World War as dark. His work highlighted four barriers to black employment prevalent at the time, namely: (1) exclusion of blacks from certain industries; (2) limited mobility or segregation within industries in which they were accepted; (3) relegation to unskilled or undesirable occupations; and (4) geographical segregation, which resulted in little to no black labor in the small cities of the North and a surplus in large northern cities. Myrdal identified race prejudice as a chief explanation of these barriers, citing three ways in which prejudice operated in the economic sphere: (1) the tendency for even well meaning whites with egalitarian values to resist competition from blacks in their own industries or unions; (2) objections by white customers opposed to being served by blacks in nonmenial positions; and (3) the belief among many white employers that blacks were simply inferior for most kinds of work.

Myrdal described the conditions of economic discrimination against blacks as self-perpetuating, arguing, “the very fact that there is economic discrimination constitutes an added motive for every individual white group to maintain such discriminatory practices” (Myrdal 1944, p. 381). His argument hinged on what he referred to as two mutually reinforcing variables, “white prejudice” and blacks’ “low plane of living,” which he believed to interact in a “vicious cycle,” a situation in which a negative factor is both cause and effect of one or more other negative factors. As he described the cycle, “on the one hand, the negroes’ plane of living is kept down by discrimination from the side of the whites while, on the other hand, the white's reason for discrimination is partly dependant on the negroes' plane of living” (Myrdal 1944, p. 1066). In other words, blacks' opportunities to transcend their relatively low standard of living were limited or cut off by white discrimination, while at the same time the low standard of living imposed on black Americans led to a host of negative outcomes such as poverty, low levels of education, and health problems, which whites pointed to as justification for continued discrimination.

This cycle is further explained through Myrdal’s use of the theory of cumulative causation. According to Myrdal, each of the attributes described above (poverty, education, health, and white prejudice against blacks), along with a host of others, is itself in a relationship of cumulative causation with all of the other attributes. For example, if an individual is denied access to education necessary to attain employment, he or she will be unable to find work in a skilled field. With only the least skilled and lowest-paid jobs available, he or she will be forced into what may be physically demanding work for little pay. The resulting physical and mental stress and poverty is likely to lead to high levels of anxiety, a poor diet, and inadequate health care, all of which can be devastating for his or her health. Frequent illness may result in an inability to hold down even the most menial of jobs, which in turn only worsens the poverty of the individual. A person in such a state may appear to be incapable of benefiting from an education, and thus educational opportunity will continue to be denied.

In Myrdal's assessment, given the interconnected relationship among these attributes and between blacks' standard of living and white prejudice and discrimination against blacks, the welfare of individual black people and of blacks in the United States was at best in a state of unstable equilibrium. The slightest change—an increase in white prejudice, a decrease in the availability of educational opportunities, loss of employment opportunities, or the onset of an illness—could send all of these attributes spiraling downward in a vicious cycle. Despite the tendency for changes in any one of these attributes to result in a vicious cycle, Myrdal suggested that the unstable equilibrium that characterized blacks' lives, though mostly negative, offered hope for reducing white prejudice and raising black Americans’ plane of living. For if any of the attributes of a black person's life were to improve, the other attributes would be expected to improve as well, and white prejudice would more than likely decrease as its justification vanished.

To this end, Myrdal proposed a campaign aimed at educating whites about their own prejudices and at attacking prejudice and discrimination everywhere they were found. In his words, “the objective of an educational campaign is to minimize prejudice—or, at least, to bring the conflict between prejudice and ideals out into the open and to force the white citizen to take his choice” (Myrdal 1944, pp. 385–386). Myrdal felt that given the choice,
most whites, especially in the North, would side with their
egalitarian ideals and that “the breakdown of discrimina-
tion in one part of the labor market [would facilitate] a
similar change in all other parts of it,” or in other words,
“the vicious cycle [could] be reversed” (p. 385).

THE AMERICAN DILEMMA AND
EDUCATION

Myrdal’s study highlighted the extreme educational disad-
vantages of African Americans in 1944. Concentrating on
the South, where the overwhelming majority of blacks
lived, he outlined the systematic efforts of whites to limit
black educational opportunities. Black schools were
underfunded, black efforts at educational empowerment
were thwarted, and black access to educational opportu-
nity was denied as part of a larger strategy to prevent
blacks from challenging white dominance. Myrdal’s An
American Dilemma placed much of the responsibility for
solving the problems of blacks on the system of education.
He argued that schools are the great levelers in American
democracy, providing equal opportunity for all regardless
of race, gender, ethnicity, region, or class origins. On the
level playing field of fair, open competition, merit would
determine who won society’s choicest prizes—prestigious
jobs, high salaries, fine homes, the good life. As evidenced
by the persistent social and economic inequality that con-
tinues to dog blacks, Myrdal’s ideal notion fails the test of
reality even today.

Despite his overly optimistic vision, Myrdal’s exami-
nation of black educational trends and problems seemed,
for the most part, to predict accurately the years following
publication of his study. However, the assimilationist
political thrust of the study also limited its predictive
power in important respects. Myrdal accurately foresaw
the formal dissolution of the dual school system in the
South. He also predicted the virulent racist reactions of
lower-class whites to increased black educational access, as
white racial privilege was threatened by the dissolution of
segregation. On these points, Myrdal’s analysis was partic-
ularly insightful and accurate. However, his assimilation-
ist approach to solving America’s race problem has not
proven sufficient to address the factors that perpetuate
racial inequities in education (e.g., residential segregation,
equal funding, inequity in quality of schooling).

In the chapter titled “The Negro Community as a
Pathological Form of the American Community,” Myrdal
argued that the African American community and its cul-
ture are essentially “distorted developments” or “patholog-
ical conditions” of the general American community and
culture. Under this reasoning, the assimilation of white
culture is the “final solution” to overcome America’s race
problem. Education would serve to change African
American culture fundamentally (i.e., remove its patho-
logical elements) and eventually bring blacks into the
larger American community: “The trend toward a rising
educational level of the Negro population is of tremen-
dous importance for the power relations discussed in this
Part of our inquiry. Education means an assimilation of
white American culture. It decreases the dissimilarity of
the Negroes from other Americans” (Myrdal 1944, p.
879). This analysis suggested that blacks and whites must
go to school together in order for blacks to assimilate into
the larger American culture. Although Myrdal’s assimila-
tionist stance saw black institutions and culture slowly
disappearing or merging with those of white America,
today black education in fact remains a separate and prob-
lematic issue. This is primarily due to the intractability of
American racial beliefs and to structured racial disad-
vantage that reinforces the social, economic, and political
underdevelopment of the black community.

In his final analysis of the “American Dilemma”
(chap. 45), Myrdal envisioned a gradual erosion of the
American caste system. While this held true with regard to
formal practices and laws, the emergence of a white back-
lash in the late 1960s and early 1970s, coupled with the
per sistence of American racial beliefs, betrayed Myrdal’s
optimistic assimilationist view. Today, the American
Dilemma is manifested in the continued failure of this
society to deliver on its promise of equal opportunity.
Despite educational gains made by African Americans
since the publication of An American Dilemma, disproporti-
nate black economic deprivation persists, as does de
c facto racial segregation and negative, stereotypic racial
beliefs about black people (Brown et al. 2003; Farley and
Allen 1989; Feagin 2006; Jaynes and Williams 1989;
Kirschenman and Neckerman 1991; Massey and Denton
1993; Schumann et al. 1985). African Americans are dis-
advantaged in the quantity and quality of education made
available to them over their lifespan. At the same time,
their hopes for progress in a society that places a premium
on educational attainment are thwarted, resulting in the
continued subordination of black people in American
society (Winfield and Woodard 1994).

As a primarily moral argument for addressing racism,
it is on these grounds that Myrdal’s work is often criti-
cized. The sociologist Oliver Cox (1901–1974) described
Myrdal’s American Dilemma as a “mystical approach to the
study of race relations,” citing his repeated references to a
common set of American values or the “American creed”
(Cox 1959, p. 509). He argued that such an approach to
the dilemma of racism in the United States fails to take
into account the material interests that sustain racism and
“may have the effect of a powerful piece of propaganda in
favor of the status quo” (p. 538). Cox put forward that
racism was in fact a system designed by the ruling politi-
cal class to maintain control over the proletariat, of what-
ever color, by distracting them from the exploitation
brought on by upper-class whites and discouraging class unity across color lines.

Describing Myrdal's stance on the solution to the American dilemma, Cox referred to the agenda of reformism, which "never goes so far as to envisage real involvement of the exploitative system with racial antagonism. Its extreme aspiration does not go beyond the attainment of freedom for certain black men to participate in the exploitation of the commonality regardless of the color of the latter" (Cox 1959, p. 535). Myrdal's American Dilemma then, as Cox saw it, was at best a useful source of data with no consistent theory of race relations or solution to the problem of racial discrimination. At worst, Myrdal's treatise represented a propaganda piece designed to reinforce class exploitation by framing racism as simply a moral problem.

Myrdal was correct in pointing to an American dilemma; however, he misconstrued this as a moral dilemma. Rather, the dilemma with which America wrestles—and has wrestled for centuries—is how best "to reconcile the practical morality of American capitalism with the ideal morality of the American Creed" (Ellison 1973, p. 83). That is, how can a system that is inherently exploitative be accommodated within the rhetoric of equality? This is a dilemma that goes beyond the black/white issues of Myrdal's time. Recently this dilemma includes how the American educational system has dealt with other nonwhite groups (Stanton-Salazar 2001). Although now far more diverse, the country's racial climate remains in many ways unchanged from the years of Myrdal's research, giving a new urgency to the questions that many felt had been answered by the immense undertaking of An American Dilemma and the subsequent period of social change. The challenge before the country now, as was the case in 1944, is "Will America commit to change and to a new, more democratic future or will the country continue to cling to its heritage of racial exploitation and oppression?" (Feagin 2006).

AMERICAN DREAM

The term American Dream traditionally has meant the ability of all Americans to attain a better standard of living, including owning a home and an automobile, and having access to higher education. The term first appeared in 1932, coined by James Truslow Adams in his book The Epic of America. In an indirect sense, it was a reaction to Theodore Dreiser's novel An American Tragedy (1925), in which the protagonist is portrayed as bent on bettering his current status in life, regardless of the consequences.

Although the term had not yet been coined, the dream became part and parcel of the national psyche during the 1920s, when consumer goods such as radios, cars, and, most importantly, homes, became readily available. To achieve widespread consumerism, manufactured items came with consumer credit offered on a revolving basis, often by the manufacturers of the goods. During that decade, about two-thirds of the gross national product...
became attributable to consumer spending; this share has persisted ever since.

The idea was aided immeasurably by political events from the 1930s through the 1970s. The concept of home ownership and mortgage credit was the first part of the dream to be given government assistance, beginning in the 1930s. Using a model first developed during World War I to aid farmers by providing standard mortgages, the Hoover administration, followed by the Roosevelt administration, began extending government intervention to the banks making residential mortgages. During the Great Depression many banks failed, and in order to preserve their assets and stabilize the market for home mortgages, Congress created several agencies dedicated to preserving the market for mortgages, to benefit both homeowners and banks. The Federal Housing Administration and the Federal National Mortgage Administration were created to guarantee home loans to banks, and the result was that mortgages were easier to obtain.

After World War II subsidized mortgages were offered by the Veterans Administration to returning servicemen, extending the concept into the postwar period. In 1957 higher education also benefited from intervention by the government when the Department of Education began offering student loans. As a result of the two programs and the modifications they underwent in the 1970s, homeownership and higher education were within the reach of many people who otherwise might not have been able to access them.

The concept has been extended to other sections of the economy as well, but the presence of government-sponsored enterprises dedicated to supporting residential mortgage loans and higher education loans attests to the enduring quality of the American Dream, both for politicians as well as social commentators. Its essential definition remains unchanged over the years.

AMERICAN ECONOMIC ASSOCIATION

The American Economic Association is the premier organization of professional economists in the world. It was organized in 1885 at a meeting in Saratoga Springs, New York. Richard T. Ely, who was active in founding the association, was its first secretary (an administrative officer) and was later a president of the association. Francis Amasa Walker, then president of the Massachusetts Institute of Technology, was its first president.

The association has three purposes: to encourage economic research, especially historical and statistical studies; to issue publications on economic subjects; and to encourage freedom of economic discussion. Because of a controversy about whether the association would be used for political advocacy that confounded its formation, the association is prohibited by charter from taking a position on practical economic questions. The spirit of these objectives has been maintained throughout the association's history.

The association's initial membership consisted mainly of college and university economics teachers. However, with growing interest in economics in the twentieth century, the association has attracted members from business and professional groups. In 2005 membership was approximately 19,000, including over 5,000 members from beyond North America. About 60 percent of members are associated with academic institutions; 20 percent with business, industry, and consulting; and 15 percent with government and not-for-profit research organizations. More than 4,000 libraries, institutions, and firms subscribed to the publications of the association in 2005.

The association employed about thirty people full-time in 2005, most involved in producing publications and organizing an annual convention. Its headquarters is in Nashville, Tennessee, and its publications office is in Pittsburgh, Pennsylvania.

Members annually receive thirteen issues of three journals: the American Economic Review, the Journal of Economic Literature, and the Journal of Economic Perspectives. The American Economic Review publishes about 100 articles a year on various economic topics chosen from among 1,200 submissions on the basis of double-blind peer review (neither author nor reviewer know the other's identity). The Journal of Economic Literature annually publishes about 20 comprehensive interpretive essays on topics that synthesize the relevant literature, and about 150 reviews of recently published books on economics. The Journal of Economic Perspectives publishes about 50 articles a year that explain current research on topics in theoretical and empirical economics or analyze public-policy issues. Articles in the Journal of Economic Perspectives are written to be accessible to an audience of...
nonspecialists. Articles in the *Journal of Economic Literature* and the *Journal of Economic Perspectives* are commissioned by the editors. The association also produces a searchable bibliography, *EconLit*, of the economic literature.

The association organizes an annual three-day conference of economists each January. About 8,000 people attend. About 1,500 research papers are presented, many of which are subsequently published in scholarly journals. The association publishes a monthly listing of job openings for economists and awards its Clark Medal biannually to the economist under age forty who has made the most important contributions to economic research. It also annually names three distinguished fellows and runs a summer program to help prepare students from underrepresented groups for PhD study in economics.

**AMERICAN INDIAN MOVEMENT**

From first contact, American Indians have striven to be treated with the respect due members of sovereign and culturally distinct nations. Governmental policy toward American Indians has shifted over the centuries from overt attempts at genocide to removal and assimilation to respect for sovereignty. By the 1950s, policy preferences were clearly in favor of acculturation and assimilation. Government boarding schools sought to help turn American Indian children into “cultural soldiers,” whose mission was to help destroy indigenous cultures from within. The national government also began to combine policies of *relocation*, moving Indians off of their reservations and into urban environments, promising help with housing and employment (promises that were more often broken than kept), and *termination*, ending official recognition of tribal status.

This combination of policies—boarding schools, relocation, and the threat of termination—led to the creation of Indian ghettos in major cities, increased incidence of social problems such as alcoholism and drug addiction, and an increased awareness of the threat to Indian resident cultures and homelands. Thus, these policies also facilitated an increasing sense among peoples of diverse tribes of both a common cause and a common enemy. That realization helped forge a common identity. American Indians did not cease thinking of themselves as members of distinct tribal communities, but many of them began to also consider themselves part of a larger whole: as “Indian” as well as Kiowa or Chickasaw.

As American Indians found themselves uprooted from their land and their cultures and facing poverty, disease, overt racism, police brutality, and other forms of discrimination, their anger at these conditions began to build. They looked to the successes of the burgeoning civil rights movement, and they too began to organize.

In 1960 Vine Deloria Jr., Clyde Warrior, Mel Thom, Shirley Witt, and Herb Blatchford formed the National Indian Youth Council, an organization explicitly based on traditional American Indian values and specifically dedicated to furthering the interests of American Indian peoples. By 1964 American Indians in the Northwest began to defend their legal and historic treaty rights through “fish-ins,” events that often led to confrontations with local citizens, governments, and police forces. Finally, in 1968, Vernon Bellecourt, his brother Clyde, and Dennis Banks incorporated the American Indian Movement (AIM) in Minneapolis, Minnesota. AIM was explicitly founded to protect local Indians from police brutality and other forms of discrimination. It soon became national, and its purpose expanded as well.

In November 1969 a group calling itself Indians of All Tribes claimed Alcatraz Island in San Francisco Bay “by right of discovery” and remained there in defiance of the federal government for nineteen months. The occupation of Alcatraz began a series of occupations of other government properties, as well as protests led by AIM leaders Dennis Banks and Russell Means at Mount Rushmore and, on Thanksgiving Day in 1970, at Plymouth Rock. Such protests signaled the beginning of increased media attention to what was styled “Indian militancy” or the “Red Power Movement.”
These protests in turn indicated the peculiar situation of American Indian activists: changing governmental policies depended, in large part, on mobilizing public sympathy, which depended on gaining public attention. That depended on keeping the attention of the media, which often also meant staging public events and maintaining public images that relied upon the prevalent stereotypes of Indian peoples—the same stereotypes activists believed contributed to the very policies they were trying to change. And in trying to change governmental policies, they were up against a powerful array of social, bureaucratic, and economic forces.

To combat these forces, AIM organized a series of caravans in 1973 that would travel the nation by separate routes, meeting in Washington, D.C., called the Trail of Broken Treaties. The caravans arrived in Washington on November 3, 1973, with a list of Twenty Points that the activists hoped to bring to the attention of the federal government. The Twenty Points included demands that the government recognize the sovereign status of Indian nations, reestablish treaty relations, and allow an Indian voice in the formation of policies regarding Indian interests.

When housing arrangements turned out to be unsuitable, the protestors converged on the Bureau of Indian Affairs (BIA) seeking assistance. They were turned away. Some of the protestors refused to leave, and ended up taking over the building, which they held for a week. The Trail of Broken Treaties, like the Alcatraz occupation, signaled the extent of the tension between the Indians, especially AIM, and the federal government. That tension escalated as many of the AIM Indians left Washington and headed for the Lakota Sioux reservation at Pine Ridge, South Dakota. Pine Ridge had long been sharply divided between those Indians favoring assimilation and accommodation with the national government and those favoring traditional Indian ways. The tribal chair, Richard Wilson, was solidly in the assimilationist camp, and was seen by the traditionalists as unfair and often violent in his treatment of them.

On February 27, 1973, a caravan of some three hundred Indians left Pine Ridge and headed for Wounded Knee, the site of a famous massacre in 1890. They occupied the small village there, and the government responded with an unprecedented show of force. The standoff continued for seventy-three days, comprised of negotiations, and led to the deaths of two Indians. Both sides considered it a moral victory, but little changed.

After Wounded Knee, the government began to escalate its actions against AIM and its leaders. Through arrests, court battles, and the operations of its COINTELPRO (counterintelligence program), which was designed to infiltrate and destroy activist organizations from within, the federal government sought to bankrupt, distract, and eliminate AIM.

The final confrontation between AIM and the federal government was also the most tragic: on June 25, 1975, FBI agents claiming to be in hot pursuit of a suspect ventured into an AIM compound on the Pine Ridge reservation. A firefight broke out, and in the melee one Indian and the two agents were killed. The rest of the Indians fled. Two (Bob Robideaux and Dino Butler) were later apprehended and tried in Cedar Rapids, Iowa, for the murder of the federal agents. An all-white jury found them not guilty. Later, a third Indian, Leonard Peltier, was also tried for the murders, was convicted, and has been in prison since 1976.

The trial of Leonard Peltier marked the end of the period of Indian activism, although not the end of AIM. AIM leaders remained active, albeit in a smaller way. Many of them have been in movies, such as Michael Apted’s Thunderheart (1992) and Incident at Oglala (1992) and the animated film Pocahontas (1995). Banks, Means, and Peltier have authored autobiographies. John Trudell, the voice of Radio Free Alcatraz, is the subject of a 2006 documentary. AIM continues to agitate, in less dramatic ways, for treaty rights, against Indian mascots, and on other issues of concern.

American National Election Studies (ANES)

The American National Election Studies (ANES) is a well-known, widely used, and broadly collaborative scientific study of elections. It focuses its efforts on providing high-quality data about voting, turnout, and participation to a wide range of social scientists. ANES data has served as the basis for hundreds of books and thousand of articles. Around the world, researchers, students, government agencies, and interested members of the public use ANES data to gain a deeper understanding of citizens and elections in the United States.

Angus Campbell, Philip E. Converse, Warren Miller, and Donald Stokes started the project in 1948. From 1952 to 1977 it was called the Michigan Election Studies and was run by the Center for Political Studies and the Survey Research Center of the Institute for Social Research at the University of Michigan. The founders introduced many valuable methodological and procedural innovations, and their book *The American Voter* is a focal reference in the study of American politics. In 1977, following an agreement with the National Science Foundation, the study was renamed the National Election Studies and has received its primary funding from the National Science Foundation ever since. This agreement stabilized the project’s funding and instituted procedures to increase the number of political scientists who contributed to the design of ANES data collections.

Throughout its history, the focal activity of ANES has been the production of a comprehensive national survey taken before and after every major election. Collectively, these studies are known as the ANES Time Series. ANES Time Series surveys are carried out via face-to-face interviews conducted in people’s homes. The combination of high response rate and carefully worded questions results in data that deeply and uniquely reflect voter perceptions and attitudes. Each survey includes many questions, including some questions that appear repeatedly over time. Such attributes allow researchers to test a wide range of hypotheses about citizen attitudes and perceptions.

In 2005 the National Science Foundation agreed to fund a substantial expansion of the project. The University of Michigan, Stanford University, and other universities are using this opportunity to give the project a new interdisciplinary emphasis. While the project’s mandate continues to be providing survey-based resources for studying voting, turnout, and participation, it is now led by a team of scholars from across the social sciences. The new ANES also features a more transparent governance and consultation structure, including the ANES Online Commons, which allows scholars to make, amend, view, and review proposals for future data collections as they are being developed. New data-collection activities include a twenty-one-month panel study. This panel interviews the same people multiple times, with the interviews starting well before the onset of presidential primary elections and ending well after the election. This strategy allows original and deeper testing of hypotheses about how and when citizens make decisions about presidential candidates and how actions taken during the election year affect public views of the new president, and hence the president’s ability to pursue new policies, in the initial months of the new president’s term.

American Political Science Association

The American Political Science Association (APSA) is a professional association of scholars from all over the world dedicated to the study of politics in all of its dimensions. The association was established in 1903 at Tulane University in New Orleans, Louisiana, and celebrated its one hundredth anniversary in Philadelphia in 2003. The one hundredth anniversary of the association’s annual convention was held in Chicago in 2004. Originally, the association was formed to distinguish a “science of politics” from the study of history and economics. In the early years, however, close cooperation with the American Historical and American Economic Associations was encouraged. The primary purpose of a separate association for political science was to “encourage” the “scientific study of politics, public law, administration and diplomacy” (Willoughby 1904, p. 109). In 2007, the associa-
The American Political Science Association (APSA) was founded in 1903 to promote research in the discipline of political science, to nurture quality teaching regarding the principles of good government and citizenship, to encourage diversification within the discipline, to provide challenging opportunities to members, to recognize outstanding contributions to the study of politics through awards programs, to develop and maintain high professional standards among scholars in the discipline, and to serve the public through the widespread dissemination of research findings.

The association is governed by a twenty-six-person council headed by a president. All members of the council and the president are elected by ballot by members of the association. A number of distinguished scholars have served as president of the APSA, including Woodrow Wilson, Charles E. Merriam, Charles A. Beard, Harold D. Lasswell, V. O. Key Jr., Carl J. Friedrich, Gabriel A. Almond, Robert Dahl, David Easton, Heinz Eulau, Samuel P. Huntington, Theodore J. Lowi, and Judith N. Shklar, the APSA’s first woman president. Ralph J. Bunche, in addition to winning the Nobel Peace Prize in 1950, became the first African American president of the APSA in 1953. With few exceptions, the addresses of presidents, a highlight at the national convention each year, are available at the APSA Web site. These addresses examine major issues and trends in the discipline and allow students of politics at all levels to gauge the perspectives and concerns of scholars, as opposed to state officials, on changing global political dynamics.

The APSA sponsors a number of programs to further its objectives. Among these is the Congressional Fellowship Program, which since 1953 has been dedicated to expanding an understanding of Congress and its operations. Participants in this program serve on Congressional staffs and include journalists and federal executives as well as political scientists. Another program provides grants of various types, such as those to assist graduate students to attend and present papers at the annual conference, and, through the Minority Fellows Program, those to assist minority students with tuition grants. Other programs provide services both to departments of political science and to individual members, such as the ejobs Placement Service. The latter service is designed to assist recent graduates of master’s and doctoral programs and current faculty on the job market to find faculty or other full-time positions.

Other major activities of the association are the publication of three journals, the American Political Science Review, Perspectives on Politics, and PS: Political Science and Politics, and the presentation of awards for outstanding scholarship in political science or outstanding public service. Among the awards are the Ralph J. Bunche Award for the best work in the previous year in the area of American ethnic studies or cultural pluralism, the James Madison Award for an American scholar who has made a particularly outstanding contribution to the study of politics, the Victoria Schuck Award for the best work in the previous year on women and politics, and the Benjamin E. Lippincott Award for a work of exceptional merit in political theory that is still considered meritorious after at least fifteen years. Awards are also given each year for the outstanding doctoral dissertations within subfields of the discipline. A highlight of the association’s activities is the annual convention, which in recent years has brought together more than 7,000 scholars participating in more than 700 panels in 47 divisions of the discipline. There are also numerous affiliated societies that regularly hold their annual conferences in conjunction with the APSA annual convention.

AMERICAN PSYCHIATRIC ASSOCIATION

SEE Post-Traumatic Stress.

AMERICAN PSYCHOLOGICAL ASSOCIATION

The American Psychological Association (APA) is the world’s largest scientific and professional association of psychologists, with 90,000 members and 65,000 student and teacher affiliates, international affiliates, and associate
members. The APA was founded on July 8, 1892, by a small group of psychologists meeting in Professor G. Stanley Hall’s study at Clark University. The thirty-one charter members, not all present at the founding meeting, were primarily scientific and academic psychologists. In the first few decades, rival associations were formed by psychologists who felt that their theoretical or professional orientations were not adequately represented in the APA. During World War II these differences were set aside and a national coordinating committee channeled the skills of the entire psychological community toward America’s war effort.

In 1945 the member organizations of the coordinating committee enacted a plan to preserve the harmony of the war years by creating a reorganized APA, governed by a council of representatives of divisions and state and provincial associations and administered by a board of directors. Division status was accorded to seventeen special interest groups and formerly independent organizations, the largest being the American Association for Applied Psychology (AAAP). The basic structure of the modern APA is composed of the governance elements created in 1945. The APA constitution provides for the creation of new divisions, and by 2006 the number of divisions had grown to fifty-six.

The reorganized APA promptly hired its first professional staff and located its headquarters in Washington, D.C., where it has occupied a series of increasingly larger buildings. In 2006 the APA employed a professional staff of nearly five hundred people and administered an annual budget of about $60 million.

Since the mid-twentieth century, growing numbers of applied psychologists have joined the organization, the majority of whom are mental health service practitioners. In the 1980s a significant number of research-oriented psychologists proposed a new reorganization of the APA that would have moderated the influence of practitioner-oriented divisions. When the proposal was not approved by the membership, the reform group founded the American Psychological Society (APS). The APS draws its members primarily from the academic and scientific communities.

The contemporary APA is a vigorous leader in many domains. The APA publishes forty-nine of the most influential scientific and professional journals in the field. It publishes a comprehensive list of books for psychological scientists, practitioners, and the general public. The APA Publication Manual, its handbook of writing standards for published articles, first appeared in 1929 and has become the standard for professional writing in many fields. The association publishes standards for the conduct of psychologists, including standards for educational and psychological testing, for the ethical treatment of humans and nonhuman animals in research, and for ethical professional conduct by psychological service providers.

After World War II the APA developed standards for professional training programs to meet the national need for well-prepared clinical psychologists. In the early twenty-first century the APA endorsed training models that combine both scientific and professional practice skills by reviewing and accrediting doctoral educational and internship programs in clinical, counseling, and school psychology. Through its liaisons with state associations of psychology, the APA has promoted rigorous state licensure standards for psychological service providers.

Since 1894 the APA has published abstracts of the world’s scientific and professional literature in psychology. This resource, called PsycINFO, is composed of more than two million abstracts and sophisticated online searching tools. The association makes full text versions of its journal articles and book chapters electronically available.

The APA has brought the science of psychology to bear on social issues. For example, it promotes awareness of ethnic minority, gender identity, and age-related concerns in educational, counseling, and clinical treatment settings, it advocates for culture-fair aptitude and achievement testing, and it promotes studies of women’s social, professional, and health-related issues. When legal cases involve critical psychological matters, the APA has filed amicus curiae briefs and has supported litigants with a legal defense fund. Among the APA’s advocacy goals are infusing federal public policy with the findings of behavioral science, extending drug prescription privileges to specially trained psychologists, and elevating support of psychological health services and research to equal that of physical health programs.

Warren R. Street
AMERICAN REVOLUTION

The American Revolution began in the early 1760s with changes in British colonial policy. Resistance opened a large problem: belonging to Britain while residing outside the British realm. The problem proved insurmountable as argument and riot led to open warfare. But virtually until independence in 1776, most rebels wanted only to stave off unwanted changes, and in this sense the Revolution was "conservative."

Abandoning British loyalty and identity forced enormous changes. Monarchy yielded to republicanism, easy to accept as an ideal but hard to work out in practice. Hierarchy beneath a king gave way to proclaimed equality. Ordinary white men who had been marginal claimed full political citizenship. White women and enslaved people of color, whom the old order had virtually excluded from public life, demanded that American liberty should apply to them, as well. Both slaves and Native Americans waged their own struggles for independence, and slavery did begin to crumble. Wartime needs gave rise to a national economy.

By the Revolution's end a separate, republican American people existed, with powerful political institutions to achieve its will. Energies had been released that would transform both the American people and the American continent. However, entirely new problems had emerged and only some of them were resolved. Others would prove as difficult as the questions on which the British Empire had floundered. In these senses, the Revolution was radical and transforming.

AN EMPIRE FALLS APART

In 1763 Britain stood triumphant over its ancient rival France. British merchant capitalism was delivering unprecedented wealth. Britons and Europeans alike celebrated British liberty, based on the premise that the British monarch could rule only with the consent of Parliament, the legislative body of Great Britain. White colonials joined in the celebrations, singing "Rule Britannia!" and huzzahing for the youthful George III (1738–1820), their "best of kings." Like their fellows in "the realm," the people of the overseas dominions were fully and proudly British.

But being British had two possible meanings. From London's viewpoint, all Britons owed obedience to the supreme authority, the king-in-parliament, which was Great Britain's absolute sovereign power. The British House of Commons represented the interests and protected the liberties of all Britons everywhere. Colonials had given little thought to such matters, but if pressed they would have said otherwise. Parliament could address large imperial questions, but their assemblies protected their local liberties and privileges. As long as Parliament did not exercise its claims, the question was effectively moot.

Defeating the French, however, had been very expensive, and British officials believed that Americans had not done their part. They also thought that the local assemblies were fractious and needed to be reined in. Some feared the northern colonies would become rivals. The answer seemed simple. Tax the colonies directly and control their economies. The money would stay in America, to pay salaries and maintain troops. But Parliament, not the local assemblies, would raise it.

The result was the Sugar Act (1764), the Stamp Act (1765), and the Townshend Acts (1767), as well as a host of administrative changes. None of the taxes matched what Britons paid at home, but they were to be paid in hard coin, which was scarce in America. Further, the new laws were to be enforced in vice-admiralty courts, whose judges could be fired and where no juries sat. The Stamp Act, in particular, threatened the well-being of the entire commercial economy. The act undercut the power of colonial elites to use finance as a weapon in their ongoing struggle with royal governors. It also threatened colonials with taxes on virtually all business transactions, to be payable in hard coin, which they simply did not have.

Colonials protested with words and deeds, and the British retreated twice. But at the end of 1773, when Bostonians destroyed three shiploads of valuable East India Company tea rather than pay the one import duty still in effect, Parliament decided that it had retreated enough. It would isolate Boston and Massachusetts and punish them severely. Shocked and in awe, the other colonies would retreat.

OLD ISSUES DIE, NEW PROBLEMS EMERGE

Instead, matters worsened. Troops occupied Boston, and people in rural areas refused to let Parliament's attempt to reform the province take effect. By the late summer of 1774, British authority in Massachusetts extended only where royal troops could march. Their commander, General Thomas Gage (1721–1787), was also the governor of the province, and he knew that rural armies were being formed. Acting under orders from London, he tried to seize a cache of supplies at Concord, Massachusetts, on April 19, 1775, along with rebel leaders who were there. Instead, he launched a war.

By that time the effort to isolate Massachusetts had failed. One Continental Congress (the federal legislature of the thirteen American colonies and later of the entire United States following the American Revolution) had met, and another was preparing to assemble. Provincial
congresses and local committees were draining power from the old institutions. People from New Hampshire to Georgia rallied to support Massachusetts. George Washington emerged as American commander and began the long task of turning a haphazard volunteer force into an army capable of facing Britain.

But for fourteen more months Americans held on to the idea that they could turn back the clock. In January 1776 Thomas Paine’s *Common Sense* argued that all monarchy needed to end and that for Americans it was “time to part.” Paine’s powerful language and vision of a transformed world reached people of all sorts, and they began to assert their own claims, challenging the ideas that the “better sort” deserved to rule the rest and that women should not have political voices, and that among America’s precious liberties was the privilege of holding slaves. Nonetheless, for many slaves and native people, the king seemed to offer a better prospect for freedom than any congress.

The Declaration of Independence was more temperate than Paine’s pamphlet. Thomas Jefferson (1743–1826), who drafted it, and Congress, which edited and adopted it, knew that attacking all monarchy would not play well with the French king, who already was giving secret aid. At the center of the document, Jefferson penned a crescendo-like indictment of “the present king of Great Britain,” presenting “facts” to a “candid world.” As his last count, Jefferson tried to blame the king both for forcing black slavery on unwilling white Americans and for encouraging slaves to rise. It was bad history and worse logic, written in tortured language. Congress dropped it, but it did demonstrate one point. Slavery was on the new republic’s agenda, ultimately to the point that it nearly destroyed what the Revolution achieved.

**THE NEW AMERICAN ORDER**

Immediately, however, the revolutionaries had to confront two urgent problems. One was winning the war. Excited by early successes and convinced of their own virtue, they expected a short conflict. But what began with a firefight in Massachusetts turned into a global conflict, involving not just France, which became an American ally in 1778, but most of Europe. The main North American war ended at Yorktown, Virginia, in 1781. The very last hostilities involving Europeans were in India. French forces first intervened there in 1778, and between 1780 and 1782. The two sides fought on the Indian mainland, Ceylon, and in Indian waters. Word of the Treaty of Paris arrived just as the British were about to lay siege to the major French stronghold, at Cuddalore, south of Madras. For native people, threatened by the American victory and abandoned by the British at the Treaty of Paris in 1783, the conflict simply continued.

Secondly, the war brought major changes, requiring a national economy in order to meet the army’s needs and creating a national elite, the men who went on to create the United States in its present form. It shook slavery, and it stimulated women, left to manage affairs, to think and act for themselves. It drove out thousands of loyalists, white, black, and native, who left rather than accept the Revolution’s triumph.

Nobody gave any thought to calling a European prince, in the way that the English had called William and Mary to the throne when they overthrew James II in 1688. There was no question that the Americans would be republican. But creating a republican order proved very difficult. Most fundamentally, it raised the problem of how to give real meaning to the idea that “the people” now were the final authority. The earliest state constitutions were simply proclaimed into effect. Not until 1780 in Massachusetts was there a popular vote on whether to accept a state’s proposed constitution. In all the states, debate raged between the idea of a remote, complex government and the idea of simple, responsive institutions. The new institutions brought men to the center of affairs who had been mere onlookers under the old order. New York split, as Vermont seceded from it, and people in the other states thought of doing the same. In 1786 Massachusetts erupted into armed conflict as farmers rose to close the courts rather than let tough fiscal policies threaten their farms. Looking around at the time, George Washington saw the danger of similar insurrections everywhere.

In 1784 Washington had seen that Americans had acquired “a mighty empire,” stretching from the Atlantic to the Mississippi and from Florida to the Great Lakes. At its center was the extremely weak Confederation Congress (the immediate successor to the Second Continental Congress), where each state had one vote and every state could veto major change. Under Congress, the United States had won the war and negotiated a very successful peace. It laid down its own colonial policy, by providing for new states in the western territories, if it could force native people out.

But in peacetime, Congress withered and men like Washington worried about the states. The result was the United States Constitution, written by a special convention in Philadelphia in 1787 and brought into effect when New Hampshire became the ninth state to ratify it in June 1788. Writing the Constitution required great creativity. Ratifying it meant hard conflict among people with widely differing visions of the American future.

Farmers, city artisans, women, slaves, and natives: All of these as well as the familiar “Founding Fathers” took part in the Revolution’s course. All of them had voices in what the Revolution wrought. Together, though rarely in agreement, they forged an unprecedented republic that
that was capitalistic and democratic, elitist and open, racist and egalitarian, imperial and inclusive, operating under a political settlement—the Constitution—that included all those qualities. They had abandoned the problems that went with being British. They solved many of the problems that rose from independence and republicanism. But they were only beginning to address the more profound social and ideological issues that their revolution raised.

**AMERICAN SOCIOLOGICAL ASSOCIATION**

Historically, the social sciences in the United States were the province of amateurs, clergy, and practitioners who belonged to the interdisciplinary American Social Science Association. During the early twentieth century, the social sciences came to be the province of academically trained PhDs working in separate disciplines. Sociology broke away from the American Social Science Association and later became part of the American Economics Association. Finally, fifty sociologists formed the American Sociological Association (ASA) in 1905. Since its founding, the ASA has grown to an organization of nearly 14,000 members. During its first 100 years, the ASA grew in complexity as well as in size as it attempted to meet members’ needs and responded to contentious as well as ordinary issues—issues that continue to affect the discipline as a whole.

**PROFESSIONALISM**

The professorate in sociology has become professionalized along several dimensions: its long training period terminating in a PhD, its claim to autonomy and freedom in research and in the classroom, its relative freedom from supervision, its body of specialized knowledge, and its adherence to a code of ethics. As of 2000, about 70 percent of sociology PhDs were employed in academia. Since 1933, especially during periods of economic downturn, the ASA or its members have attempted to develop positions for professional sociologists outside of the professorate. These efforts, an effort to control the labor supply, were buttressed by claims about the overproduction of PhDs. At the same time, there were strong feelings that practicing sociology outside of the academy, especially in political or business settings, compromised scientific objectivity and theoretical rigor. The distinction between scientific sociology and client-oriented sociology decreased with the growth of pressure for academics to seek outside funding and with the increase in state-mandated accountability and assessment requirements for faculty. The most recent rewriting of the ASA Code of Ethics bound both academic and nonacademic sociologists to avoid conflicts of interest, assure confidentiality, and respect people’s “rights, dignity, and diversity.”

**ACADEMIC FREEDOM**

Because norms of autonomy and control are important in research and teaching, the ASA developed institutional mechanisms for dealing with issues of academic freedom. In the early years, the ASA joined with the American Economics Association and the American Political Science Association in a Committee on Academic Freedom and Academic Tenure. This committee produced one report. During the 1950s, members of the ASA passed a resolution at the annual business meeting “deploring such discriminatory requirements” as loyalty oaths on account of the special interest of social scientists in inquiring about controversial social, political, and economic issues. In the 1980s the ASA’s elected Council founded the Committee on Freedom in Research and Teaching (COFRAT) to protect individual freedom of research and teaching. During the 1980s this committee served in a fact-finding capacity on individuals’ complaints against institutions and recommended institutional sanctions if warranted. These efforts became increasingly acrimonious as institutions protested COFRAT’s work. A committee appointed to review COFRAT’s mission recommended that COFRAT should
deal with systematic abuses rather than individual cases. COFRAT reported difficulty in monitoring systematic or institutional conditions and became increasingly inactive. When the ASA restructured in the late 1990s, COFRAT was discontinued.

SPECIALIZATION
As its membership grew, there were internal pressures for the ASA to respond to members’ requests for new projects, services, and processes. In so responding, the association became more a complex organization composed of an Executive Office, standing committees, and single-issue task forces. Growth also brought a proliferation of new membership subgroups, “sections” formed around substantive, theoretical, and methodological specialty areas. By 2005 there were forty-two sections, with most members joining at least one section. The larger sections include Medical Sociology; Sex and Gender; Organizations, Occupations, and Work; Sociology of Culture; Theory; and Family. Some members argue that the diversity of sections reflects the fragmentation of the discipline. Others, however, claim that the growth of sections promotes networking within the organization. While the number of specialty sections increased within the association, the ASA continued to participate in such multidisciplinary institutional efforts as the Social Science Research Council, the American Council of Learned Societies, and the Council of Social Science Associations.

SOCIAL PRACTICE
Early U.S. sociologists often engaged deeply in public issues. The writings and activism of Lester Ward, W. E. B. Du Bois, and Jane Addams affected public debate on such issues as racism, poverty, employment conditions, feminism, and social welfare. Others practiced sociology in the public arena by writing reports for courts, health departments, foundations, and government agencies. Social activism was criticized as “unscientific” by academic sociologists who enjoyed higher status, assumed leadership positions, and published in leading journals. Over time, public sociologists tried to legitimate their work. In the 1980s they petitioned for a practice section within the ASA, initiated a short-lived journal of practice, and pressed for a task force that would create bridges to the public sphere. In 2004 a new task force on “institutionalizing public sociology” was formed to provide rewards and incentives to “bring sociology to publics beyond the academy.” During this time, debate resurfaced about whether the ASA should take sides on political issues. Although the membership did not endorse an antiwar resolution in 1968, they endorsed positions favoring the withdrawal of troops from Iraq in 2003 and opposing a Constitutional amendment banning gay marriage. In response to the debate, the ASA’s Council developed criteria requiring scientifically supported evidence before putting hot-button issues before the membership for final approval.

TEACHING
Since the ASA’s inception, debates about the sociology curriculum concerned not only content and teaching methods but also whether the craft of teaching is rewarded and respected on par with scholarly pursuits. During the 1970s the ASA Executive Office opened a Teaching Resource Center; added teaching workshops to the annual meeting; awarded grants for enhancing teaching; formed a departmental visitation program to improve curricula, teaching, and the status of the craft; and began a new journal, Teaching Sociology. These activities paralleled a growing movement to develop a scholarship of teaching and learning that challenged the denigration of teaching within academia.

GENDER
Only one woman attended the founding meeting of the ASA. Since then, women’s involvement within the ASA increased dramatically, though not without a struggle. By 1944 about 25 percent of PhD-level sociologists were women, although the percentage decreased until the late 1960s. As the number of sociology doctorates awarded to women increased, feminists worked to change both the substance of the field and their treatment within it. After women engaged in sit-ins, founded a separate organization (Sociologists for Women in Society), held an alternative convention, and formed a Women’s Caucus, the ASA’s Council responded by establishing a standing Committee on the Status of Women in Sociology in 1971. ASA members successfully petitioned to create a specialty section on the study of sex and gender, now among the largest ASA sections. Later in the decade, the first annual Jessie Barnard Award was given “in recognition of scholarly work enlarging the horizons [of sociology] to encompass fully the role of women in society.” At the centennial of the ASA, women received about 60 percent of all sociology PhDs. Yet the 2004 report of the Committee on the Status of Women in Sociology to the Council presented evidence suggesting that women are a “majority minority” in the discipline—not equally represented at the discipline’s highest ranks, facing chilly climates at work, experiencing uneven policies to balance work and family, and relatively ignored in ASA journals that include few articles on women’s issues.

RACE AND ETHNICITY
Papers on race relations, racial attitudes, cultural differences among races, and the concept of race as a social cat-
egory have been presented at every annual meeting since 1907. According to many African American and Hispanic sociologists, the growth of sociology in the United States was related to studies of the problems of racial and minority groups rather than to struggles for social justice. With the growth of the civil rights movement, an ad hoc group was formed to increase the visibility and the voice of minority sociologists within the ASA. The Black Caucus formed in 1969, and by the 1970 annual meeting it had presented a number of resolutions, including one for the establishment of a program to provide stipends for graduate training. Independently of the ASA, the Association of Black Sociologists was formed in 1970 to promote “scholarship that will serve Black people in perpetuity.” The ASA responded to these efforts throughout the 1970s. A specialist in racial and minority relations was hired, the Council instituted the Du Bois-Johnson-Frazier Award, and it later created a standing Committee on the Status of Race and Ethnicity. In the wake of a Black Caucus recommendation, a training grant from the National Institute of Mental Health has provided stipends for nearly 400 doctoral students of color since 1974. The ASA has continued to address race and ethnic issues by participating in the Clinton Administration’s Initiative on Race, producing the ASA Statement on the Importance of Collecting Data and Doing Research on Race, and presenting an amicus brief to the Supreme Court for Grutter v. Bollinger, a case concerning affirmative action at the University of Michigan’s Law School. Despite these efforts, in response to a recent review of sociology in its 100th year, James Blackwell, a renowned black sociologist, noted that members of minority groups remain tokens at most traditionally white colleges and universities. That may not change in the near future. Even as late as 2003, only 32 of 106 graduate programs awarded a doctorate of sociology to an African American, and only 18 programs awarded a doctorate to a Hispanic.

In the beginning of its second hundred years, the ASA continues to face both ordinary and contentious issues raised by sociologists of diverse positions and interests as it attempts to meet their professional needs, advance the discipline, and engage the public.

AMERICANISM

Americanism is an ideology that holds that the cultural and political values of the United States are the most ideal and desirable of any in the world. It is closely linked with American exceptionalism, a phrase coined by Alexis de Tocqueville (1805–1859) in 1831. Tocqueville argued that, because of its historical evolution, national credo, historical origins, and distinctive political and religious institutions, the United States is qualitatively different from other nations. Some have characterized Americanism and its beliefs as a “civic religion.”

Seymour Lipset identifies five key elements of Americanism: liberty, egalitarianism, individualism, populism, and laissez-faire. He avers, “Being an American,
Americanism

Americanism is an ideological commitment. It is not a matter of birth. Those who reject American values are un-American” (Lipset 1997, p. 31). Americanism emphasizes equality of opportunity, as opposed to equality of outcomes, and attaches greater importance to social and political individualism.

American veneration of these ideals grew out of the country’s historical development and the distinctive role of Protestantism. John Winthrop (1588–1649), governor of the Massachusetts Bay Colony, described the early Puritan community in New England as a “city on a hill” with which God had made a special covenant. According to Winthrop, the early colony should serve as a moral and political example for the rest of the world. The American Revolution (1775–1783), with its emphasis on democracy, liberty, and republicanism, is often cited as proof that the United States offers unlimited potential and opportunity to those who work hard. Americanism is often associated with manifest destiny, the idea that Americans had a mission from God to spread liberty and democracy across the American frontier and around the world. Later, supporters of Americanism have pointed to the durability of the U.S. Constitution, the failure of socialist parties to come to power, and Americanism’s appeal to those who work hard. Americanism is often associated with manifest destiny, the idea that Americans had a mission from God to spread liberty and democracy across the American frontier and around the world. Later, supporters of Americanism have pointed to the durability of the U.S. Constitution, the failure of socialist parties to come to power, and Americanism’s appeal to those who work hard.

Theodore Roosevelt (1858–1919) greatly popularized Americanism. In an 1894 magazine article, he wrote that “no other land offers such glorious possibilities to the man able to take advantage of them as does ours” (1897, pp. 38–39). He argued that any person could become an American, provided they adopted the American beliefs in democracy, hard work, capitalism, and egalitarianism; learned English; and left behind their previous sectarian identities. Roosevelt encouraged immigration to the United States, but with the proviso that immigrants fully embrace the American way of life. He also adopted these same ideals in his foreign policies, leading American military involvement in Cuba and the Philippines under the guise of bringing liberation, democracy, and the American way of life to these countries.

During both world wars, German and Japanese communities in the United States came under suspicion for not fully believing in American values and identifying too closely with their homelands. This resulted in both relatively harmless colloquial changes (renaming sauerkraut “liberty cabbage”) and overtly discriminatory policies like the forced internment of twelve thousand ethnic Japanese (most of whom were U.S. citizens) in camps throughout the western United States during World War II (1939–1945). Later, during the cold war, mass media and government officials often juxtaposed Americanism with Communism as a battle between liberty and tyranny.

President George W. Bush has relied on Americanism arguments to justify American operations in Iraq, positing that the United States is freeing the Iraqi people from tyranny and delivering American-style democracy and liberty.

In recent years, Americanism has been at the heart of the debates about legal and illegal immigration. Samuel Huntington (2004) has argued that immigration, primarily from Latin America, threatens the very character of American society because recent immigrants remain too attached to their homelands, refusing to learn English or adopt American beliefs in hard work, individual responsibility, and capitalism.

Critics have long chastised Americanism for relying on a selective, uncritical reading of U.S. history. They point out that the United States itself often fails to uphold Americanist ideals for its own citizens through such means as denying voting rights, restricting citizenship, and promoting discriminatory policies. This hypocrisy not only undermines the argument that egalitarianism and liberty are at the heart of the American experience, but also calls into question whether the United States can (or should) promote these values to other countries. Others have called Americanism imperialism cloaked in a rhetoric of values and human rights. They also question the use of military force in places like the Philippines, Vietnam, and Iraq to promote democracy and liberty.

Americanism shares some commonalities with both nationalism and patriotism, as well as three attack positive values to one’s home country and its upholding of national beliefs and symbols. In a critical distinction, though, Americanism specifies the nature of the United States’ distinctness from the rest of the world. Further, Americanism allows that persons born outside the United States can become Americans if they adopt American beliefs; nationalism often holds that one’s membership in a nation is determined by birth and remains constant throughout life.

AMIN, IDI
c. 1925–2003

Idi Amin became the president of Uganda in January 1971 after a military coup removed the elected leader, Milton Obote, and he fled into exile to Saudi Arabia on April 11, 1979 after a war with Tanzania. In the intervening eight years his name became synonymous with mass murder, destruction, militarism, and the worst features of political misrule in Africa.

Idi Amin was born in northwest Uganda in 1925 or 1926; that his birthdate is imprecise illustrates the marginalization and isolation of the peoples of that part of Uganda under British colonial rule. Britain had claimed Uganda as a protectorate at the end of the nineteenth century, and Uganda was integrated into the East African Command of the King’s African Rifles (KAR). Later the events of Amin’s life became more precise—the records show that he was recruited into the KAR in 1946, one year after the end of World War II. Amin was deployed by the British to participate in the counterinsurgency war against the freedom fighters in Kenya, and there he engaged in brutality and wanton murder against Africans. Based in the Muranga region of Kenya between 1953 and 1956, Amin learned all of the techniques of low-intensity warfare when the British incarcerated more than 1.5 million Kenyans and hanged thousands.

Idi Amin was both a pugilist and militarist; from 1951 to 1960 he was the light heavyweight boxing champion of Uganda. He also rose through the colonial army, eventually attaining the rank of effendi (warrant officer), the highest rank that a black African could attain in the KAR at that time. The Uganda that became independent in 1962 was plagued with deep divisions based on regional, religious, and ethnic alliances. Because of uneven colonial penetration, the areas in the south of the country—including the precolonial kingdoms of Ankole, Buganda, Bunyoro, Toro, and Busoga—were more involved with colonial cash crops, and hence in these regions there was a higher proportion of Africans educated by the missionary schools. These regional differences were interpreted in ethnic terms, so much of the writings on Uganda portrayed Idi Amin as coming from the tribally backward north. This social reality was compounded by the fact that there were close to 100,000 Asians who dominated the interstices of the colonial economy and owned sugar and tea plantations. At the time of independence in 1962 there was not a single black African wholesaler on the main business street in Kampala, the capital.

Amin was promoted rapidly in the Ugandan army, becoming general and commander in 1966. By 1969 the social divisions in Uganda had deepened to the point where Obote’s government increasingly depended on the military to maintain its power. The military was mobilized against trade unions, against village cooperatives, against cattle rustlers, against political opponents, and against students.

The military coup of January 25, 1971, took place while the prime minister, Milton Obote, was attending a Commonwealth summit meeting in Singapore. The military takeover immediately plunged the society into a bloodbath. The coup could not have been consolidated without the support of imperial security networks, especially those of Britain and Israel, and later, records showed that the governments of Israel and Britain were indeed involved in planning, executing, and defending the military coup in January 1971.

The relations between Britain and Uganda changed one year later, however, when Amin declared an economic war, which involved the expulsion of more than 80,000 Asian citizens who held British passports. Many Asians (primarily of Indian origin) owned businesses in Uganda, and by deporting them Amin gained domestic political support amid increased repression in the society. But their expulsion placed Amin on a collision course with the West, and brought the conditions of the people of Uganda to the attention of the international media.

At the height of the cold war, Amin became the chairperson of the Organization of African Unity (OAU). The selection of Amin was possible, in large part, because of the divisions unleashed by the cold war in Africa. The Soviet Union supported leaders who declared themselves to be anti-imperialist. When Amin had seized power in the 1971 military coup, Uganda was diplomatically allied to the United States, Israel, and the United Kingdom. After the expulsion of the Asians in 1972, Uganda became a close ally of Libya, Saudi Arabia, and the Soviet Union. Inside Africa, Amin formed a close alliance with known butchers and militarists such as Mobutu Sese Seko of Zaire and Michel Micombero of Burundi. In the same year Amin expelled the Asians, Micombero carried out genocide in his own country, killing more than 300,000 citizens. The selection of Amin to be the chairperson of the OAU brought disgrace to the organization insofar as Amin used the clause of noninterference in the internal affairs of states to prevent pan-African intervention to stop the killings.

The killings and wanton destruction of lives in Uganda intensified between 1972 and 1978, and it has been estimated that by the end of his regime Amin had killed more than 300,000 Africans (another estimate puts the number as high as 500,000). In addition, there were more than one million Ugandans living in exile in neighboring countries.

The Ugandan army invaded Tanzania and occupied the Kagera province in October 1978, precipitating the war between Uganda and Tanzania. The Tanzanian army
counterattacked and supported Ugandan exiles in launching their own counteroffensive (as the Uganda National Liberation Army, or UNLA) against the Amin regime. At the end of this war, in April 1979, when the combined forces of the Tanzanian army and the UNLA took Kampala, Amin fled the city to exile, first in Libya, then in Saudi Arabia, where he lived until his death in August 2003.

When Amin came to power in 1971 he had been hailed as an archetypal common man, and Western social scientists had declared that Uganda's military government could serve as a model for modernization in Africa; Makerere University in Kampala was a veritable laboratory for the ideas of modernization and nation-building. But Amin's regime left a tradition of destruction, low respect for human life, and cross-border warfare that is still plaguing the regions of eastern and central Africa. The continuing war between the Ugandan government and the Lord's Resistance Army, a rebel paramilitary group in northern Uganda, remains one of the outstanding legacies of this period of militarism, masculinity, and warfare.

AMIN, SAMIR
1931–

Samir Amin was born in Cairo, the son of two doctors, his father Egyptian and his mother French. He lived in Port Said in northern Egypt and attended the French lycée there, receiving his baccalaureate in 1947. Amin then enrolled at the Lycée Henri IV in Paris to study mathematics and at the Institut d'études Politiques to study law, which at the time was the way to study economics. He received a diploma in political science in 1952 and a license in law and economics in 1953 and then opted to pursue a doctorate in economics. He also obtained a diploma in statistics from the Institut de Statistiques de l'Université de Paris in 1956. In June 1957, Amin received a doctorate in economics under the direction of Maurice Byé and with the additional guidance of François Perroux. As a student, Amin spent much of his time as a militant with various student movements and from 1949 to 1953 helped publish the journal Étudiants Anticolonialistes, through which he met many of the future members of Africa's governing elite.

From 1957 to 1960, Amin worked in Cairo on economic development issues for the Egyptian government, then moved to Bamako, Mali, where he was an adviser to the Malian planning ministry (1960–1963). In 1963 he moved to Dakar, Senegal, where he took a fellowship (1963–1970) at the Institut Africain de Développement Économique et de Planification (IDEP). He became a director at IDEP (1970–1980) and subsequently was named director of the Third World Forum (1980–). Amin has at various times held professorships in Poitiers, Dakar, and Paris.

The author of more than thirty books, Amin's brilliant 1957 dissertation, subsequently published in 1970 as L'accumulation à l'échelle mondiale; critique de la théorie du sous-développement (translated in 1974 as Accumulation on a World Scale: A Critique of the Theory of Underdevelopment), was the earliest significant work to argue that underdevelopment in much of the world was a direct consequence of the way the capitalist economy functions. He argued that this polarization is due to transfers of profits from the poor countries to the rich, which help alleviate potential underconsumptionist problems in the industrial economies, allowing the industrial world to pay higher salaries or offer lower prices to consumers than would be possible were the labor theory of value to work simply at the national level.

Amin's new emphasis on the global economy as a unit of analysis is intended to explain global salary and price differences within a Marxist labor theory of value. Even his later works (e.g. Obsolescent Capitalism and Beyond U.S. Hegemony) have built on this model to critique imperialist projects generally and post–September 11, 2001 U.S. hegemonic efforts more particularly. Amin argues for a polycentric world that can counteract monopolies in areas such as technology, finance, natural resources, media, and weapons production that consistently hurt poor countries.

Amin's reliance on a labor theory of value and underconsumptionist theory has limited his analytical outlook and led him to make overly simplistic predictions even as it has allowed a holistic historical materialistic perspective. Nevertheless, his criticisms of neoclassical equilibrium
models and imperialistic projects have long since been joined by those of economists and social scientists from many different theoretical persuasions.

ANARCHISM

Anarchism is a theory and way of life rooted in the belief that the individual should be free to pursue his or her own interests without coercion, especially by the state and its laws and institutions. The term is derived from the ancient Greek word anarkhia, meaning “no ruler,” and originally was used to denote a disruption of the normal civic order that often implied a condition of civil war. As with democracy and democrat, the words anarchy and anarchist were typically used as terms of abuse until the nineteenth century, when with the rise of commercial society and the decline of feudalism the idea of self-rule by “the people” became increasingly accepted.

The political theory of anarchism properly begins only with William Godwin (1756–1836) and Pierre-Joseph Proudhon (1809–1865), though important elements of anarchist thought can be found in the ancient Greeks, among them Aristippus of Cyrene (c. 435–c. 360 BCE) and the founder of Stoicism, Zeno of Citium (c. 334–262 BCE). Strains of anarchist thought can also be found in the medieval era, in the Anabaptists of the Reformation, and in the Diggers of the English Revolution of the mid-seventeenth century. However, Godwin is the first exponent of the philosophic doctrine of anarchism, though he does not use the term anarchist to describe himself; it is Proudhon who first calls himself an anarchist. In Proudhon’s What Is Property? (1840) he lays out a vision of socialism in which the individual is liberated from the shackles of capitalist property relations, and is instead free to reap the benefits of his labor under a form of communal production. Anarchism became increasingly relevant to the political world of the late nineteenth and early twentieth centuries, first through the writings of Mikhail Bakunin (1814–1876), who opposed the overly centralized socialism of Karl Marx (1818–1883), and later through Peter Kropotkin (1842–1921) and Emma Goldman (1869–1940).

Anarchist thought is extremely diverse, but is generally characterized by opposition to the state, capitalism, and religion. Rather than seeing the legal apparatus of the state as a means of protecting individual freedom, anarchists contend that the state and its laws merely represent the self-serving interests of powerful groups in society. In this view, law is a means of oppressing the vast majority of the people, and the best way to eliminate this oppression is to do away with the institutions that create and reinforce it—especially the state and private property. Private property is a particular concern for anarchists, in that it corrupts the democratic process by controlling the inputs and outputs to the political system, and also because it directs people to think merely about their own self-interest rather than about how to cooperate with their fellow citizens. Because private property uses the state to benefit...
Anarchists promote their goals by multiple means, including sometimes violent revolution, but also through democratic evolution and the creation of independent communal societies that function outside the domain of the state. In the Spanish Civil War (1936–1939) anarchists and anarcho-syndicalists (linked industrial worker-councils) formed an important element in the opposition to Francisco Franco’s fascist coup, and shared governmental authority with a socialist coalition, particularly in Barcelona. This experiment, though short-lived, provided an example of anarchist “government” in practice, and was characterized by the liquidation of the landed estates and the parceling of the land into agricultural cooperatives, the establishment of a federation of worker-controlled factories, and the elimination of the social indications of class status that had marked Bourbon Spain. Although defeated in the war, Spanish anarchism continues to be a model for other nations, because it is here that one of the largest worker-run cooperatives in the world, the Mondragon Cooperative Corporation, has been functioning for more than fifty years.

Among anarchists in the early part of the twenty-first century there are several prominent trends, some of which are substantially in tension with one another. Libertarian anarchists such as Murray Rothbard (1926–1995) defend capitalism, arguing that the protection of private property under capitalism provides the surest foundation for promoting individual liberty. Unlike most libertarians, Rothbard claims that even the most minimal state is an unnecessary evil, but this is almost the only thing that unites him with anarchist-socialists such as the protesters at the World Trade Organization (WTO) and G8 meetings in Seattle in 1999 and Geneva in 2001. Though not united by a systematic program, these protesters represented groups that are dissatisfied with the current system of neoliberal trade promoted by the WTO, which to them represents an extension of the rule of private property over the globe.

Anarchism is not highly visible in most developed western nations, but it remains a powerful underground current that both the Left and the Right continue to find useful as a stimulant to political thought and political action. Anarchism will continue to be relevant as long as the meaning of the terms democracy, property, and freedom is not self-evident.

ANDERSON, PERRY

1938–

Perry Anderson (born in 1938) is one of the most important Marxist authors of the past forty years. As the principal editor of New Left Review since 1962, he has introduced and shaped English-language readers’ understanding of the principal Western European Marxist theorists of the twentieth century, above all the Italian Antonio Gramsci, whose concept of hegemony is now central to Marxist scholarship. Under Anderson’s guidance, New Left Review has brought the work of European and third-world Marxists to a broader public of intellectuals and activists. New Left Review has also published continuous analysis of contemporary political economy and culture that seeks to find openings for leftist politics and provides criticism of contemporary social scientists, philosophers, novelists, and artists. In addition, Anderson has made a major scholarly contribution to the understanding of England’s particular political development and to the analysis of European absolutism.

Anderson’s political orientation was shaped by two events of 1956 (the year he arrived at Oxford University as a student): the Soviet crushing of the Hungarian Revolution and the Israeli, French, and British invasion of Egypt. He was part of the New Left, which condemned both Soviet repression and Western imperialism against
Egypt. Anderson, throughout his intellectual career, has argued that contemporary politics needs to be understood in the context of the historical development of states and classes. He has contributed to such a historical-materialist analysis through his study of the formation of the English state. His aptly titled "Origins of the Present Crisis," published in *New Left Review* in 1964, explains the failure of British socialism in terms of England’s unusual historical trajectory, especially its lack of a bourgeois revolution. His analysis quickly came under attack from historian E. P. Thompson on both empirical and theoretical grounds (“The Peculiarities of the English”). Anderson responded with *Arguments within English Marxism* (1980), a book-length analysis of Thompson. Written as an appreciation and critique of Thompson's historical and political writings, Anderson sees Thompson’s main contribution as a reassertion of the importance of culture and morality in socialist intellectual discussions. Anderson believes that Thompson slights the search for effective strategies of socialist politics. That is the task to which Anderson has devoted himself and *New Left Review* in recent years.

Anderson’s greatest intellectual contribution is his study of absolutist states and their role in the development of the European bourgeoisie. *Passages from Antiquity to Feudalism*, the first volume of Anderson’s study of transitions, provides the context for his analysis of feudalism in *Lineages of the Absolutist State*. *Passages* explores the dynamics of the slave mode of production and explains variations in feudalism across Europe in terms of divisions in the Roman Empire and the sorts of class struggle that erupted during the empire’s decline. *Lineages of the Absolutist State* (1974) reconceived the social dynamics that followed the Black Death of the fourteenth century (the liberalization of peasant obligations in England and France and the reimposition of serfdom in much of Eastern Europe). Feudalism, in Anderson’s analysis, was neither destroyed nor replaced by a new mode of production. Instead, feudalism was reconstituted, as the aristocracy reasserted its dominance through the larger social form of the absolutist state rather than within local manors.

Anderson views the bourgeoisie as an inadvertent outcome of absolutist state polices designed by aristocrats to safeguard their collective interests. Both state and capital grew and profited from the monetization of taxes and rents, the sale of state offices, and the establishment of protected domestic monopolies and colonial ventures. Anderson explains the different trajectories of Eastern European and Western European states, and of England and France, in terms of the strength of aristocrats’ organization within estates, the extent of town autonomy, and the results of military competition. He was able to show how a new social group, the bourgeoisie, developed at particular sites within certain absolutist states, yet he never attempted to explain why the bourgeoisie was unable to continue to pursue its interests within absolutism. As a result, *Lineages*, despite its significant insights, was not able to serve as the foundation for Anderson’s planned but as yet unwritten study of the bourgeois revolutions. Since the early 1980s Anderson has moved away from historical studies and has concentrated his writings on contemporary politics and criticism.

**ANIMISM**

According to animism, all phenomena—everything that is seen, heard, touched, or felt; every animal, plant, rock, mountain, cloud, or star, and even tools and implements—are believed to possess a soul, which is understood to be conscious and endowed with an ability to communicate. Considered the original or first human religion, animism originates from the Latin *anima*, meaning
Animism

“soul,” which comes from the earlier Greek word *animus*, meaning “wind” or “breath.” It is defined as belief in spiritual beings or entities that are thought to give all things, both animate and inanimate, a certain kind of potency or life force.

Animism is a primal belief system dating back to the Paleolithic era, yet it is estimated that 40 percent of the world’s population still practices some form of animism, often in syncretism with Christianity, Islam, Buddhism, and Hinduism. Contemporary people find animism a belief system that infuses their real-life situation with the sacred and provides guidance in addressing everyday problems, concerns, and needs, such as healing sickness, bringing success, or receiving guidance. Animism can be practiced by anyone who acknowledges the existence of spirits, but it does not require any affiliation with an organized religion.

As the first human thought system to interface with the nonhuman or spirit realms, animism recognizes an ontological connection between material things and their spiritual source. The artifacts and remains that document the symbolic nature of animism are unimaginably old, created long before human culture gave birth to language and recorded history. For millions of years humans have deified ancestors, animals, plants, stones, rivers, and stars, each of which was thought to be enlivened by a particular “anima” or soul, having the capacity to leave the body both during life and after death.

Animism was not discovered, created, or developed by any one individual or group; instead, it was a way of living in reciprocity with the larger natural environment and not separate from it. Indigenous people followed a kind of rudimentary animism that served many functions. Not only did animism provide answers to pressing philosophical questions—how the universe came into being, the nature of the forces operating within it, the origins of the ancestors—but also it addressed more immediate issues concerning how to live, how to die, and what happens in the afterlife.

Shaman was the name given to the holy men and women who were considered sacred leaders called on to sustain the tribe’s connection to the spirit realm and the land of the dead. Shamans were able to navigate through various cosmic levels so as to ensure that all things in nature were kept interdependent and integral to the whole universe. The basis of animism is an acknowledgement of a spiritual realm, within the physical world, that humans share with the cosmos. To become a shaman required that one have special proximity to the spirit world. Using preternatural powers, trance, ritual, dance, and shamanic “journeys,” the shaman ensured that the relation between the human community and the natural ecosystem it cohabited was reciprocal and mutual.

Western philosophical schools have employed the term *animism* to describe an awareness of a living presence within all matter. Aristotle’s idea supporting the relation of body and soul was animistic, as was Plato’s belief in an immaterial force behind the universe. Gottfried Wilhelm Leibniz (1646–1716) and Arthur Schopenhauer (1788–1860) expanded the notion of animism with the assertion that all substances are essentially force, tendency, and dynamism. The modern concept of vitalism challenges the idea that all phenomena can be traced back to chemical and mechanical processes and offers a perspective that presupposes an animistic understanding of human nature and the natural world. In his work *Primitive Culture* (1871), Edward B. Tyler coined the term *animism* to refer to the original form of human spirituality and the first primitive religion. In this book, he described primitive religion as operating at a lower level of cognitive and social development than more evolved religions with coherent, systematic theologies. Primitive religion is now understood in a less ethnocentric way and is valued for its direct link to the primal mind. Today those practicing animism see themselves as part of the natural world rather than the masters and rulers of it.

Animism is emerging as a critical voice in response to the ecological crisis and is a serious topic that science, technology, and the social sciences must consider. Many in search of a new spirituality are discovering animism to offer a world view that is naturally connected to the earth, nature, and broader ecosystem. Animism fosters an attitude that reinforces living respectfully with all things.

ANNEXATION

Annexation is the physical takeover of conquered territories as part of a greater state policy of expansionism. In most cases, annexation begins with the occupation of a subordinate territory through military possession and ends with formal political recognition of the acquisition by both parties involved. In some cases, the involved parties seek a cooperative agreement either to avoid war or because they recognize a common benefit through shared political, economic, and social institutions. The process of annexation, however, is usually driven by coercive measures: a compelling use or physical threat of force, intimidation or fear tactics, and other means of direct or indirect pressure. Annexation may produce either a long-lasting or a temporary political, economic, and social relationship between two states.

States that adopt annexationist policies are driven to satisfy their “land hunger” through the acquisition of lands that are outside of their original borders. These lands may be adjacent to the annexing state and represent the fulfillment of irredentist or nationalist goals. For example, Germany's annexation of Austria and the Sudetenland in 1938 was part of a larger foreign policy aiming to unite all Germanic peoples under one larger empire. This policy of national expansion also directed the United States' annexation of Texas in 1845. In this case, annexation was at the heart of the United States' greater policy of Manifest Destiny; it believed that “winning the West” was part of fulfilling its natural destiny in North America. States may also seek to expand their colonial empire through the annexation of foreign territories. The annexation of Madagascar by France in 1896 illustrates this form of expansionism. In 1868 a treaty between the Merina peoples and the French government designated Madagascar as a French protectorate. British recognition of this arrangement in 1890 legitimized the French presence on the island, but only after France's defeat of the Merina army in 1895 did Madagascar become fully annexed by France.

In either case, the expansion of national influence through the physical acquisition of land, peoples, and natural resources drives a state’s annexationist policies. The absence of international laws that regulate annexation allows each state to develop its own process of annexation. Some states’ annexationist policies are or have been governed by domestic national law, as was the case with Italy's 1936 annexation of Ethiopia, which occurred with a formal decree issued by the king of Italy, and the United States' acquisitions of Texas (1845) and Hawaii (1898), which were directed by joint resolutions in the U.S. Congress. Other states do not or have not constructed a legal framework for determining the process of annexation. For example, Japan completed the annexation of its Korean protectorate in 1910 through a simple proclamation by the emperor. Only the illegal use of force is condemned by the charter of the United Nations.

Annexed regions become part of the greater entity when the sovereign authority of the annexing state is recognized by both parties. Even though annexationist policy is a form of unilateral politics—a one-sided agreement imposed by the dominant party—the process of annexation is complete once a legitimization of the acquisition is accepted by the international community. In some cases, international treaties may aid in the process of annexation, as in the case of Norway's annexation of the Svalbard Islands in 1925. The terms of the country’s final configuration, however, are determined solely by the annexing state. For example, the annexing state has the right to force the citizens of the annexed territory to adopt new national laws and customs. In many instances, the process of annexation leads to the destruction of the subordinate territory's cultural identity. For example, the annexation of Hawaii by the United States and the subsequent declaration of Hawaiian statehood in 1959 have resulted in the Americanization of the Hawaiian Islands. Many native populations of permanently annexed lands have dedicated themselves to the preservation of their culture through peaceful educational movements or active resistance to deculturation.

Conversely, annexationist policies may be underscored by distinct humanitarian goals. A dual desire to promote industrial growth in the South and greater racial equality in American society as a whole drove the annexationist program of Northern Radical Republicans at the end of the U.S. Civil War (1861–1865). These abolitionist politicians advocated a program of Reconstruction that included the annexation of Southern states with the express purpose of destroying plantation society and establishing a unified liberal capitalist federal nation. In this case, the politics of annexation reflected a desire for the institutionalization of Radical Republican Judge Albion Tourgée's (1838–1905) philosophy of “color-blind justice” for freed persons of the South and should be noted for its progressive commitment to social justice.

Annexation is not the inevitable outcome of military conquest, but rather one of many possible outcomes of conquest. For example, the military occupation of Germany and Japan after World War II (1939–1945) did not lead to the annexation of either country by the Allied powers. In both cases the Allies expressly rejected annexation of the subordinate territories at the time of occupation. Annexation can therefore be seen as a calculated, deliberate domestic or international policy.

ANTHROPOLOGY

Anthropology is the study, analysis, and description of humanity’s past and present. Questions about the past include prehistoric origins and human evolution. Study of contemporary humanity focuses on biological and cultural diversity, including language. Compared to other disciplines that address humanity such as history, sociology, or psychology, anthropology is broader in two ways. In terms of humanity’s past, anthropology considers a greater depth of time. In terms of contemporary humans, anthropology covers a wider diversity of topics than other disciplines, from molecular DNA to cognitive development and religious beliefs.

This depth and breadth correspond to the wide variety of sites and contexts in which anthropologists conduct research. Some anthropologists spend years in harsh physical conditions searching for fossils of early human ancestors. Others live among and study firsthand how people in Silicon Valley, California, for example, work, organize family life, and adapt to a situation permeated by modern technology. Anthropologists may conduct analyses in a laboratory studying how tooth enamel reveals an individual’s diet, or they may work in a museum, examining designs on prehistoric pottery. Yet other anthropologists observe chimpanzees in the wild.

Research methods in anthropology range from scientific to humanistic. In the scientific mode, anthropologists proceed deductively. They formulate a hypothesis, or research question, and then make observations to see if the hypothesis is correct. This approach generates both quantitative (numeric) data and qualitative (descriptive) data. In the humanistic approach, anthropologists proceed inductively, pursuing a subjective method of understanding humanity through the study of people’s art, music, poetry, language, and other forms of symbolic expression. Anthropologists working in the humanistic mode avoid forming a hypothesis, and they rely on qualitative information.

No matter whether it is conducted in a rainforest settlement or a university laboratory, or pursued from a scientific or a humanistic perspective, research in anthropology seeks to produce new knowledge about humanity. Beyond generating knowledge for its own sake, anthropology produces findings of relevance to significant contemporary issues. Knowledge in anthropology is of value to government policy makers, businesses, technology developers, health care providers, teachers, and the general public.

FOUR-FIELD ANTHROPOLOGY IN NORTH AMERICA

In North America anthropology is defined as a discipline comprising four fields that focus on separate but interrelated subjects. The subjects are archaeology, biological anthropology (or physical anthropology), linguistic anthropology, and cultural anthropology (or social anthropology). Some North American anthropologists argue that a fifth field, applied anthropology, should be added. Applied anthropology, also called practicing or practical anthropology, is the use of anthropological knowledge to prevent or solve problems, or to shape and achieve policy goals. The author of this essay takes the
position that the application of knowledge is best conceived of as an integral part of all four fields, just as theory is, rather than placed in a separate field.

The depth and breadth of anthropology have both positive and negative implications. The advantages of the depth and breadth of the four-field approach are the same as those that accrue to any kind of multidisciplinary work that requires thorough dialogue across domains about theories, methods, findings, and insights. Such dialogue tends to advance thinking in original and fruitful ways. Those who do not support anthropology as a four-field discipline point to the disadvantages of combining so much depth and breadth in one discipline. The main issue here is the differences between the scientific and humanistic approaches to understanding humanity.

In North America, the four-field approach is maintained to a large extent in the departmental organization and degree requirements at larger colleges and universities, and in professional associations such as the American Anthropological Association (AAA) and the Canadian Sociology and Anthropology Association (CSAA). Some notable splits in departments occurred in the late nineteenth century. In 1998, the former single Department of Anthropology at Stanford University divided into the Department of Cultural and Social Anthropology and the Department of Anthropological Sciences, with the former focusing on humanistic anthropology and the latter on scientific anthropology. Duke University has a Department of Cultural Anthropology and a Department of Biological Anthropology and Anatomy. Archaeology is housed within the Department of Classics. In some North American universities archaeology is a separate department, but anthropology is generally housed in anthropology departments.

Outside North America the four fields exist in separate academic units. The word “anthropology” in such contexts often refers only to biological anthropology. The English term “ethnology” or its equivalent in other languages corresponds to North American cultural anthropology. “Folklore” studies continue to be important in many European countries and in Japan. Linguistic anthropology is less prominent outside North America.

Archaeology Archaeology means, literally, the “study of the old,” with a focus on human culture. Archaeology, which began in Europe in the nineteenth century, centers on the excavation and analysis of artifacts, or human-made remains. Depending on one’s perspective about valid evidence for the first humans, the time-depth of archaeology goes back to the beginnings of early humans with the earliest evidence of human-made tools approximately two million years ago.

Archaeology encompasses two major subfields: prehistoric archaeology and historical archaeology. Prehistoric archaeology covers the human past before written records. Prehistoric archaeologists identify themselves according to major geographic regions: Old World archaeology (Africa, Europe, and Asia) or New World archaeology (North, Central, and South America). Historical archaeology deals with the human past in societies that have written documents.

Another set of specialties within archaeology is based on the context in which the research takes place. One such specialty is underwater archaeology, which is the study and preservation of submerged archaeological sites. Underwater archaeological sites may be from either prehistoric or historic times. Industrial archaeology focuses on changes in material culture and society during and since the Industrial Revolution. Industrial archaeology is especially active in Great Britain, home of the industrial revolution. In Great Britain industrial archaeologists study such topics as the design and construction of iron bridges, the growth and regional distribution of potteries and cloth mills, and workers’ housing.

Worldwide, archaeologists seek to preserve the invaluable remains of humanity’s cultural heritage of the past, and therefore archaeology has a strong applied component. Applied archaeologists work in a variety of domains. Many archaeologists are employed in cultural resource management, assessing possible archaeological remains before such construction projects as roads and buildings can proceed. Industrial archaeologists contribute to the conservation of endangered sites that are more likely to be neglected or destroyed than sites that have natural beauty or cultural glamour attached to them. Archaeologists are becoming increasingly involved in making findings relevant to local people and to improving their welfare. Collaborative archaeology projects that involve community members in excavation, analysis, stewardship, and financial benefits are a growing trend.

Biological Anthropology Biological anthropology, or physical anthropology, is the study of humans as biological organisms, including their evolution and contemporary variation. The history of biological anthropology was strongly influenced by the work of Charles Darwin (1809–1882), especially his theories of evolution and species survival through competition. The three subfields of biological anthropology are primatology, paleoanthropology, and contemporary human biology. The three subfields share an interest in the relationship between morphology (physical form) and behavior.

Primatology is the study of the order of mammals called primates, including human and nonhuman primates. The category of nonhuman primates includes a
Anthropology

A wide range of animals from small, nocturnal creatures to gorillas, the largest members. Primatologists record and analyze how animals spend their time; collect and share food; form social groups; rear offspring; deal with conflict; and how all of these are affected by captivity.

Paleoanthropology is the study of human evolution on the basis of the fossil record. Paleoanthropologists search for fossils to increase the amount and quality of evidence related to how human evolution occurred. Genetic evidence suggests that human ancestors diverged from the ancestors of chimpanzees between five and eight million years ago in Africa. Fossil evidence for the earliest human ancestors is scarce for this period and researchers are searching for fossils to fill the gap. An equally important activity of paleoanthropologists is labwork focused on dating, reconstructing, and classifying fossils.

Anthropologists who study contemporary human biology define, measure, and seek to explain similarities and variation in the biological makeup and behavior of modern humans. Topics include diet and nutrition, fertility and reproduction, physical growth and health over the life cycle, and urban stress and pollution. Genetic and molecular analyses are of growing interest and importance for tracing similarities and differences in human biology including susceptibility to certain health conditions such as sickle cell anemia, Down syndrome, and diabetes.

Biological anthropology has many applied aspects. Applied primatologists provide data for designing nonhuman primate conservation projects. Paleoanthropologists serve as advocates for programs to protect fossil sites from looting and to ensure that important fossils and knowledge about them are part of public education. Biological anthropologists with specialized knowledge of human anatomy work in forensics, identifying crime victims and providing expert testimony in courts. Many forensic anthropologists are involved in investigations of human rights abuses around the world. Biological anthropologists in the subfield of contemporary human biology provide knowledge relevant to development projects seeking to improve people’s nutrition and health.

Linguistic Anthropology Linguistic anthropology is the study of communication, mainly among humans but also among other animals. Linguistic anthropology emerged in Europe and North America in the latter half of the nineteenth century. At that time its major topics of interest were the origins of language, the historical relationships of languages of different regions and continents, and the languages of “primitive” peoples.

Two factors shaped linguistic anthropology in its early days: the discovery that many non-European languages were unwritten and the realization that the languages of many non-European peoples were dying out as a consequence of contact with Europeans. Linguistic anthropologists responded to the discovery of unwritten languages by developing methods for recording unwritten and dying languages. They learned that non-European languages have a wide range of phonetic systems (pronunciation of various sounds) that do not correspond to those of Western languages. Linguistic anthropologists invented the International Phonetic Alphabet, which contains symbols to represent all known human sounds. In response to the discovery of dying languages, many early linguistic anthropologists devoted efforts to recording dying languages in work that is called “salvage anthropology.”

Linguistic anthropology has three subfields. The first, historical linguistics, is the study of language change over time, how languages are related, and the relationship of linguistic change to cultural change. The second is descriptive or structural linguistics. This subfield is the study of how contemporary languages differ in terms of their structure, such as in grammar and sound systems. The third subfield is sociolinguistics, the study of the relationships among social variation, social context, and linguistic variation, including nonverbal communication. Sociolinguistics is closely related to cultural anthropology and some North American anthropologists rightfully claim expertise in both fields.

Beginning in the 1980s, four new directions emerged in sociolinguistic anthropology. First is a trend to study language in everyday use, or discourse, in relation to power structures at local, regional, and international levels. For example, in some contexts, powerful people speak more than less powerful people, while in other contexts more powerful people speak less. Second, globalization has prompted new areas of inquiry include the study of “world languages” such as English, Spanish, and the emerging role of Chinese. Third, study of the media is a major growth area with attention to the relationship between language and nationalism, the role of mass media in shaping culture, mass communication and violence, and the effects of the Internet and cell phones on identity and social relationships. Fourth, linguistic anthropologists are increasingly focusing on language rights as human rights.

Applied roles for linguistic anthropologists are expanding. One professional area is education policy and school curriculum. Applied linguistic anthropologists consult with educational institutions about how to meet the needs of multicultural school populations and improve standardized tests for bilingual populations. They conduct research on classroom dynamics, such as student participation and teachers’ speech patterns, in order to assess possible biases related to ethnicity, gender, and class. Applied linguistic anthropologists contribute to the recovery of “dead” and declining languages as invaluable cul-
Cultural Anthropology Cultural anthropology is the study of the culture, or the learned and shared behavior and beliefs of groups of living humans. Prominent subfields within cultural anthropology are economic anthropology, medical anthropology, psychological anthropology, kinship and family studies, social organization and social stratification, political anthropology, legal anthropology, religion, communication, expressive culture, and development anthropology.

History. The earliest historical roots of cultural anthropology are in the writings of Herodotus (fifth century BCE), Marco Polo (c. 1254–c. 1324), and Ibn Khaldun (1332–1406), people who traveled extensively and wrote reports about the cultures they encountered. More recent contributions come from writers of the French Enlightenment, such as eighteenth century French philosopher Charles Montesquieu (1689–1755). His book, Spirit of the Laws, published in 1748, discussed the temperament, appearance, and government of non-European people around the world. It explained differences in terms of the varying climates in which people lived.

The mid- and late nineteenth century was an important time for science in general. Influenced by Darwin’s writings about species’ evolution, three founding figures of cultural anthropology were Lewis Henry Morgan (1818–1881) in the United States, and Edward Tylor (1832–1917) and James Frazer (1854–1941) in England. The three men supported a concept of cultural evolution, or cumulative change in culture over time leading to improvement, as the explanation for cultural differences around the world. A primary distinction in cultures was between Euro-American culture (“civilization”) and non-Western peoples (“primitive”). This distinction is maintained today in how many North American museums place European art and artifacts in mainstream art museums, while the art and artifacts of non-Western peoples are placed in museums of natural history.

The cultural evolutionists generated models of progressive stages for various aspects of culture. Morgan’s model of kinship evolution proposed that early forms of kinship centered on women with inheritance passing through the female line, while more evolved forms centered on men with inheritance passing through the male line. Frazer’s model of the evolution of belief systems posited that magic, the most primitive stage, is replaced by religion in early civilizations which in turn is replaced by science in advanced civilizations. These models of cultural evolution were unilinear (following one path), simplistic, often based on little evidence, and ethnocentric in that they always placed European culture at the apex. Influenced by Darwinian thinking, the three men believed that later forms of culture are inevitably superior and that early forms either evolve into later forms or else disappear.

Most nineteenth century thinkers were “armchair anthropologists,” a nickname for scholars who learned about other cultures by reading reports of travelers, missionaries, and explorers. On the basis of readings, the armchair anthropologist wrote books that compiled findings on particular topics, such as religion. Thus, they wrote about faraway cultures without the benefit of personal experience with the people living in those cultures. Morgan stands out, in his era, for diverging from the armchair approach. Morgan spent substantial amounts of time with the Iroquois people of central New York. One of his major contributions to anthropology is the finding that “other” cultures make sense if they are understood through interaction with and direct observation of people rather than reading reports about them. This insight of Morgan’s is now a permanent part of anthropology, being firmly established by Bronislaw Malinowski (1884–1942).

Malinowski is generally considered the “father” of the cornerstone research method in cultural anthropology: participant observation during fieldwork. He established a theoretical approach called functionalism, the view that a culture is similar to a biological organism wherein various parts work to support the operation and maintenance of the whole. In this view a kinship system or religious system contributes to the functioning of the whole culture of which it is a part. Functionalism is linked to the concept of holism, the perspective that one must study all aspects of a culture in order to understand the whole culture.

The “Father” of Four-Field Anthropology. Another major figure of the early twentieth century is Franz Boas (1858–1942), the “father” of North American four-field anthropology. Born in Germany and educated in physics and geography, Boas came to the United States in 1887. He brought with him a skepticism toward Western science gained from a year’s study among the Innu, indigenous people of Baffin Island, Canada. He learned from that experience the important lesson that a physical substance such as “water” is perceived in different ways by people of different cultures. Boas, in contrast to the cultural evolutionists, recognized the equal value of different cultures and said that no culture is superior to any other. He introduced the concept of cultural relativism: the view that each culture must be understood in terms of the values and ideas of that culture and must not be judged by the standards of another. Boas promoted the detailed study of
individual cultures within their own historical contexts, an approach called historical particularism. In Boas’s view, broad generalizations and universal statements about culture are inaccurate and invalid because they ignore the realities of individual cultures.

Boas contributed to the growth and professionalization of anthropology in North America. As a professor at Columbia University, he hired faculty and built the department. Boas trained many students who became prominent anthropologists, including Ruth Benedict and Margaret Mead. He founded several professional associations in cultural anthropology and archaeology. He supported the development of anthropology museums.

Boas was involved in public advocacy and his socially progressive philosophy embroiled him in controversy. He published articles in newspapers and popular magazines opposing the U.S. entry into World War I (1914–1918), a position for which the American Anthropological Association formally censured him as “un-American.” Boas also publicly denounced the role of anthropologists who served as spies in Mexico and Central America for the U.S. government during World War I. One of his most renowned studies, commissioned by President Theodore Roosevelt (1858–1919), was to examine the effects of the environment (in the sense of one’s location) on immigrants and their children. He and his research team measured height, weight, head size and other features of over 17,000 people and their children who had migrated to the United States. Results showed substantial differences in measurements between the older and younger generations. Boas concluded that body size and shape can change quickly in response to a new environmental context; in other words, some of people’s physical characteristics are culturally shaped rather than biologically (“racially”) determined.

Boas’ legacy to anthropology includes his development of the discipline as a four-field endeavor, his theoretical concepts of cultural relativism and historical particularism, his critique of the view that biology is destiny, his anti-racist and other advocacy writings, and his ethical stand that anthropologists should not do undercover research.

Several students of Boas, including Mead and Benedict, developed what is called the “Culture and Personality School.” Anthropologists who were part of this intellectual trend documented cultural variation in modal personality and the role of child-rearing in shaping adult personality. Both Mead and Benedict, along with several other U.S. anthropologists, made their knowledge available to the government during and following World War II (1939–1945). Benedict’s classic 1946 book, *The Chrysanthemum and the Sword* was influential in shaping U.S. military policies in post-war Japan and in behavior toward the Japanese people during the occupation. Mead likewise, offered advice about the cultures of the South Pacific to the U.S. military occupying the region.

The Expansion of Cultural Anthropology. In the second half of the twentieth century cultural anthropology in the United States expanded substantially in the number of trained anthropologists, departments of anthropology in colleges and universities, and students taking anthropology courses and seeking anthropology degrees at the bachelor’s, master’s, and doctoral level. Along with these increases came more theoretical and topical diversity.

Cultural ecology emerged during the 1960s and 1970s. Anthropologists working in this area developed theories to explain cultural similarity and variation based on environmental factors. These anthropologists said that similar environments (e.g., deserts, tropical rainforests, or mountains) would predictably lead to the emergence of similar cultures. Because this approach sought to formulate cross-cultural predictions and generalizations, it stood in clear contrast to Boasan particularism.

At the same time, French anthropologist Claude Lévi-Strauss (b. 1908) developed a different theoretical perspective influenced by linguistics and called structuralism. Structuralism is an analytical method based on the belief that the best way to learn about a culture is by analyzing its myths and stories to discover the themes, or basic units of meaning, embedded in them. The themes typically are binary opposites such as life and death, dark and light, male and female. In the view of French structuralism these oppositions constitute an unconsciously understood, underlying structure of the culture itself. Lévi-Strauss collected hundreds of myths from native peoples of South America as sources for learning about their cultures. He also used structural analysis in the interpretation of kinship systems and art forms such as the masks of Northwest Coast Indians. In the 1960s and 1970s French structuralism began to attract attention of anthropologists in the United States and has had a lasting influence on anthropologists of a more humanistic bent.

Descended loosely from these two contrasting theoretical perspectives—cultural ecology and French structuralism—are two important approaches in contemporary cultural anthropology. One approach, descended from cultural ecology, is cultural materialism. Cultural materialism, as defined by its leading theorist Marvin Harris (1927–2001), takes a Marxist-inspired position that understanding a culture should be pursued first by examining the material conditions in which people live: the natural environment and how people make a living within particular environments. Having established understanding of the “material” base (or infrastructure), attention may then be turned to other aspects of culture, including social organization (how people live together in groups, or...
structure) and ideology (people’s way of thinking and their symbols, or superstructure). One of Harris’ most famous examples of a cultural materialist approach is his analysis of the material importance of the sacred cows of Hindu India. Harris demonstrates the many material benefits of cows, from their plowing roles to the use of their dried dung as cooking fuel and their utility as street-cleaning scavengers, underly and are ideologically supported by the religious ban on cow slaughter and protection of even old and disabled cows.

The second approach in cultural anthropology, descended from French structuralism and symbolic anthropology, is interpretive anthropology or interpretivism. This perspective, championed by Clifford Geertz (1926–2006), says that understanding culture is first and foremost about learning what people think about, their ideas, and the symbols and meanings important to them. In contrast to cultural materialism’s emphasis on economic and political factors and behavior, interpretivists focus on webs of meaning. They treat culture as a text that can only be understood from the inside of the culture, in its own terms, an approach interpretivists refer to as “experience near” anthropology, in other words, learning about a culture through the perspectives of the study population as possible. Geertz contributed the concept of “thick description” as the best way for anthropologists to present their findings; in this mode, the anthropologist serves as a medium for transferring the richness of a culture through detailed notes and other recordings with minimal analysis.

Late Twentieth and Turn of Century Growth. Starting in the 1980s, several additional theoretical perspectives and research domains emerged in cultural anthropology. Feminist anthropology arose in reaction to the lack of anthropological research on female roles. In its formative stage, feminist anthropology focused on culturally embedded discrimination against women and girls. As feminist anthropology evolved, it looked at how attention to human agency and resistance within contexts of hierarchy and discrimination sheds light on complexity and change. In a similar fashion, gay and lesbian anthropology, or “queer anthropology,” has exposed the marginalization of gay and lesbian sexuality and culture in previous anthropology research and seeks to correct that situation.

Members of other minority groups voice parallel concerns. African American anthropologists have critiqued mainstream cultural anthropology as suffering from embedded racism in the topics it studies, how it is taught to students, and its exclusion of minorities from positions of power and influence. This critique has produced recommendations about how to build a non-racist anthropology. Progress is occurring, with one notable positive change being the increase in trained anthropologists from minority groups and other excluded groups, and their rising visibility and impact on the research agenda, textbook contents, and future direction of the field.

Another important trend is increased communication among cultural anthropologists worldwide and growing awareness of the diversity of cultural anthropology in different settings. Non-Western anthropologists are contesting the dominance of Euro-American anthropology and offering new perspectives. In many cases, these anthropologists conduct native anthropology, or the study of one’s own cultural group. Their work provides useful critiques of the historically Western, white, male discipline of anthropology.

At the turn of the twenty-first century, two theoretical approaches became prominent and link together many other diverse perspectives, such as feminist anthropology, economic anthropology, and medical anthropology. The two approaches have grown from the earlier perspectives of cultural materialism and French structuralism, respectively. Both are influenced by postmodernism, an intellectual pursuit that asks whether modernity is truly progress and questions such aspects of modernism as the scientific method, urbanization, technological change, and mass communication.

The first approach is termed structurism, which is an expanded political economy framework. Structurism examines how powerful structures such as economics, politics, and media shape culture and create and maintain entrenched systems of inequality and oppression. James Scott, Nancy Scheper-Hughes, Arthur Kleinman, Veena Das, and Paul Farmer are pursuing this direction of work. Many anthropologists use terms such as social suffering or structural violence to refer to the forms and effects of historically and structural embedded inequalities that cause excess illness, death, violence, and pain.

The second theoretical and research emphasis, derived to some extent from interpretivism, is on human agency, or free will, and the power of individuals to create and change culture by acting against structures. Many anthropologists avoid the apparent dichotomy in these two approaches and seek to combine a structurist framework with attention to human agency.

The Concept of Culture Culture is the core concept in cultural anthropology, and thus it might seem likely that cultural anthropologists would agree about what it is. Consensus may have been the case in the early days of the discipline when there were far fewer anthropologists. Edward B. Tylor (1832–1917), a British anthropologist, proposed the first anthropological definition of culture in 1871. He said that “Culture, or civilization … is that complex whole which includes knowledge, belief, art, law, morals, custom, and any other capabilities and habits acquired by man as a member of society” (Kroeber and
Kluckhohn 1952, p. 81). By the 1950s, however, an effort to collect definitions of culture produced 164 different definitions. Since that time no one has tried to count the number of definitions of culture used by anthropologists.

In contemporary cultural anthropology, the theoretical positions of the cultural materialists and the interpretive anthropologists correspond to two different definitions of culture. Cultural materialist Marvin Harris defines culture as the total socially acquired life-way or life-style of a group of people, a definition that maintains the emphasis on the holism established by Tylor. In contrast, Clifford Geertz, speaking for the interpretivists, defines culture as consisting of symbols, motivations, moods, and thoughts. The interpretivist definition excludes behavior as part of culture. Again, avoiding a somewhat extreme dichotomy, it is reasonable and comprehensive to adopt a broad definition of culture as all learned and shared behavior and ideas.

Culture exists, in a general way, as something that all humans have. Some anthropologists refer to this universal concept of culture as “Culture” with a capital “C.” Culture also exists in a specific way, in referring to particular groups as distinguished by their behaviors and beliefs. Culture in the specific sense refers to “a culture” such as the Maasai, the Maya, or middle-class white Americans. In the specific sense culture is variable and changing. Sometimes the terms “microculture” or local culture are used to refer to specific cultures. Microcultures may include ethnic groups, indigenous peoples, genders, age categories, and more. At a larger scale exist regional or even global cultures such as Western-style consumer culture that now exists in many parts of the world.

Characteristics of Culture Since it is difficult to settle on a neat and tidy definition of culture, some anthropologists find it more useful to discuss the characteristics of culture and what makes it a special adaptation on which humans rely so heavily.

Culture is based on symbols. A symbol is something that stands for something else. Most symbols are arbitrary, that is, they bear no necessary relationship to that which is symbolized. Therefore, they are cross-culturally variable and unpredictable. For example, although one might guess that all cultures might have an expression for hunger that involves the stomach, no one could predict that in Hindi, the language of northern India, a colloquial expression for being hungry says that “rats are jumping in my stomach.” Our lives are shaped by, immersed in, and made possible through symbols. It is through symbols, especially language, that culture is shared, changed, stored, and transmitted over time.

Culture is learned. Cultural learning begins from the moment of birth, if not before (some people think that an unborn baby takes in and stores information through sounds heard from the outside world). A large but unknown amount of people’s cultural learning is unconscious, occurring as a normal part of life through observation. Schools, in contrast, are a formal way to learn culture. Not all cultures throughout history have had formal schooling. Instead, children learned culture through guidance from others and by observation and practice. Longstanding ways of enculturation, or learning one’s culture, include stories, pictorial art, and performances of rituals and dramas.

Cultures are integrated. To state that cultures are internally integrated is to assert the principle of holism. Thus, studying only one or two aspects of culture provides understanding so limited that it is more likely to be misleading or wrong than more comprehensively grounded approaches. Cultural integration and holism are relevant to applied anthropologists interested in proposing ways to promote positive change. Years of experience in applied anthropology show that introducing programs for change in one aspect of culture without considering the effects in other areas may be detrimental to the welfare and survival of a culture. For example, Western missionaries and colonists in parts of Southeast Asia banned the practice of head-hunting. This practice was embedded in many other aspects of culture, including politics, religion, and psychology (i.e., a man’s sense of identity as a man sometimes depended on the taking of a head). Although stopping head-hunting might seem like a good thing, it had disastrous consequences for the cultures that had practiced it.

Cultures Interact and Change Several forms of contact bring about a variety of changes in the cultures involved. Trade networks, international development projects, telecommunications, education, migration, and tourism are just a few of the factors that affect cultural change through contact. Globalization, the process of intensified global interconnectedness and movement of goods, information and people, is a major force of contemporary cultural change. It has gained momentum through recent technological change, especially the boom in information and communications technologies, which is closely related to the global movement of capital and finance.

Globalization does not spread evenly, and its interactions with and effects on local cultures vary substantially, from positive change for all groups involved to cultural destruction and extinction for those whose land, livelihood and culture are lost. Current terms that attempt to capture varieties of cultural change related to globalization include hybridization (cultural mixing into a new form) and localization (appropriation and adaptation of a global form into a new, locally meaningful form).
ETHNOGRAPHY AND ETHNOLOGY
Cultural anthropology embraces two major pursuits in its study and understanding of culture. The first is ethnography or “culture-writing.” An ethnography is an in-depth description of one culture. This approach provides detailed information based on personal observation of a living culture for an extended period of time. An ethnography is usually a full-length book.

Ethnographies have changed over time. In the first half of the twentieth century, ethnographers wrote about “exotic” cultures located far from their homes in Europe and North America. These ethnographers treated a particular local group or village as a unit unto itself with clear boundaries. Later, the era of so-called “village studies” in ethnography held sway from the 1950s through the 1960s. Anthropologists typically studied in one village and then wrote an ethnography describing that village, again as a clearly bounded unit. Since the 1980s, the subject matter of ethnographies has changed in three major ways. First, ethnographies treat local cultures as connected to larger regional and global structures and forces; second, they focus on a topic of interest and avoid a more holistic (comprehensive) approach; and third, many are situated within industrialized/post-industrialized cultures.

As topics and sites have changed, so have research methods. One innovation of the late twentieth century is the adoption of multi-sited research, or research conducted in more than one context such as two or more field sites. Another is the use of supplementary non-sited data collected in archives, from Internet cultural groups, or newspaper coverage. Cultural anthropologists are turning to multi-sited and non-sited research in order to address the complexities and linkages of today’s globalized cultural world. Another methodological innovation is collaborative ethnography, carried out as a team project between academic researchers and members of the study population. Collaborative research changes ethnography from study of people for the sake of anthropological knowledge to study with people for the sake of knowledge and for the people who are the focus of the research.

The second research goal of cultural anthropology is ethnology, or cross-cultural analysis. Ethnology is the comparative analysis of a particular topic in more than one cultural context using ethnographic material. Ethnologists compare such topics as marriage forms, economic practices, religious beliefs, and childrearing practices, for example, in order to discover patterns of similarity and variation and possible causes for them. One might compare the length of time that parents sleep with their babies in different cultures in relation to personality. Researchers ask, for example, if a long co-sleeping period leads to less individualistic, more socially connected personalities and if a short period of co-sleeping produces more individualistic personalities. Other ethnological analyses have considered the type of economy in relation to frequency of warfare, and the type of kinship organization in relation to women’s status.

Ethnography and ethnology are mutually supportive. Ethnography provides rich, culturally specific insights. Ethnology, by looking beyond individual cases to wider patterns, provides comparative insights and raises new questions that prompt future ethnographic research.

CULTURAL RELATIVISM
Most people grow up thinking that their culture is the only and best way of life and that other cultures are strange or inferior. Cultural anthropologists label this attitude ethnocentrism: judging other cultures by the standards of one’s own culture. The opposite of ethnocentrism is cultural relativism, the idea that each culture must be understood in terms of its own values and beliefs and not by the standards of another culture.

Cultural relativism may easily be misinterpreted as absolute cultural relativism, which says that whatever goes on in a particular culture must not be questioned or changed because no one has the right to question any behavior or idea anywhere. This position can lead in dangerous directions. Consider the example of the Holocaust during World War II in which millions of Jews and other minorities in much of Eastern and Western Europe were killed as part of the German Nazis’ Aryan supremacy campaign. The absolute cultural relativist position becomes boxed in, logically, to saying that since the Holocaust was undertaken according to the values of the culture, outsiders have no business questioning it.

Critical cultural relativism offers an alternative view that poses questions about cultural practices and ideas in terms of who accepts them and why, and who they might be harming or helping. In terms of the Nazi Holocaust, a critical cultural relativist would ask, “Whose culture supported the values that killed millions of people on the grounds of racial purity?” Not the cultures of the Jewish people, the Roma, and other victims. It was the culture of Aryan supremacists, who were one subgroup among many. The situation was far more complex than a simple absolute cultural relativist statement takes into account, because there was not “one” culture and its values involved. Rather, it was a case of cultural imperialism, in which one dominant group claimed supremacy over minority cultures and proceeded to change the situation in its own interests and at the expense of other cultures. Critical cultural relativism avoids the trap of adopting a homogenized view of complexity. It recognizes internal cultural differences and winners/losers, oppressors/victims. It pays attention to different interests of various power groups.
APPLIED CULTURAL ANTHROPOLOGY

In cultural anthropology, applied anthropology involves the use or application of anthropological knowledge to help prevent or solve problems of living peoples, including poverty, drug abuse, and HIV/AIDS. In the United States, applied anthropology emerged during World War II when many anthropologists offered their expertise to promote U.S. war efforts and post-war occupation. Following the end of the war, the United States assumed a larger global presence, especially through its bilateral aid organization, the U.S. Agency for International Development (USAID). USAID hired many cultural anthropologists who worked in a variety of roles, mainly evaluating development projects at the end of the project cycle and serving as in-country anthropologists overseas.

In the 1970s cultural anthropologists worked with other social scientists in USAID to develop and promote the use of “social soundness analysis” in all government-supported development projects. As defined by Glynn Cochrane, social soundness analysis required that all development projects be preceded by a thorough baseline study of the cultural context and then potential redesign of the project based on those findings. A major goal was to prevent the funding of projects with little or no cultural fit. The World Bank hired its first anthropologist, Michael Cernea, in 1974. For three decades, Cernea influenced its policy-makers to pay more attention to project-affected people and their culture in designing and implementing projects. He promoted the term “development induced displacement” to bring attention to how large infrastructure projects negatively affect millions of people worldwide and he devised recommendations for mitigating such harm.

Many cultural anthropologists are applying cultural analysis to large-scale institutions (e.g., capitalism and the media) particularly their negative social consequences, such as the increasing wealth gap between powerful and less powerful countries and between the rich and the poor within countries. These anthropologists are moving in a new and challenging direction. Their work involves the study of global–local interactions and change over time, neither of which were part of cultural anthropology’s original focus. Moreover, these cultural anthropologists take on the role of advocacy and often work collaboratively with victimized peoples.

Anthropologists are committed to documenting, understanding, and maintaining cultural diversity throughout the world as part of humanity’s rich heritage. Through the four-field approach, they contribute to the recovery and analysis of the emergence and evolution of humanity. They provide detailed descriptions of cultures as they have existed in the past, as they now exist, and as they are changing in contemporary times. Anthropologists regret the decline and extinction of different cultures and actively contribute to the preservation of cultural diversity and cultural survival.

**SEE Anthropology, Public.**

**ANTHROPOLOGY, BIOLOGICAL**

Biological anthropology is concerned with the origin, evolution and diversity of humankind. The field was called physical anthropology until the late twentieth century, reflecting the field’s primary concern with cataloging anatomical differences among human and primate groups. Under the name of biological anthropology, it is an ever-broadening field that encompasses the study of: human biological variation; evolutionary theory; human origins and evolution; early human migration; human ecology; the evolution of human behavior; paleoanthropology; anatomy; locomotion; osteology (the study of skeletal material); dental anthropology; forensics; medical anthropology, including the patterns and history of disease; primatology (the study of non-human primates); growth, development and nutrition; and other related fields.

The kinds of questions that biological anthropologists ask include:

What makes humans different from other species?

Where did modern humans arise and when?

What does evidence show about the original human migrations throughout the world?

What kinds of biological differences exist between populations, including anatomical, genetic, and behavioral, or patterns of growth and
development, and how did the biological differences arise?
What can we learn about human evolution and behavior from non-human primates or other species?
How did uniquely human traits such as bipedalism and language evolve?
What can molecular genetics add to the understanding of evolution and human variation?
How does normal development happen, and what can it contribute to knowledge about evolution?

METHODS

Biological anthropology has a rich collection of methods, new and old, for answering these questions. Methods used include: field methods for finding specimens; comparative anatomy and morphological measurement; fossil analysis; population genetics; demographic and epidemiologic methods; and the use of model animals such as mice or non-human primates. Modern technologies—computed tomography (CT) scanning, molecular genetic and bioinformatic analytic techniques—are used to address questions about human diversity with studies of DNA variation and its history, for example. Tiny details of bones and fossils can be visualized and compared with high-powered imaging techniques to yield clues about the evolution of various traits.

In the late twentieth century, the largest change in biological anthropology has been the rapid incorporation of modern genetics. There are genetics laboratories in anthropology departments around the world, working on a wide variety of questions concerning human origins and diversity. Anthropologists also collaborate with non-anthropologists who have expertise in a broad spectrum of technical fields in order to use a wide variety of methodologies in their research.

HISTORY

Although people have been interested for several millennia in characterizing how populations differ, the work of Swedish botanist Carolus Linnaeus (1707–1778) cataloging all known species was the first modern systematic classification of human variation. Linnaeus developed the binomial naming convention (Homo sapiens, for example) still used today. He classified humans into groups based on geographic origin and skin color, and subsequently on behavior. Probably not surprisingly, Europeans ranked highest in Linnaeus’s schemes.

A number of people worked on cataloging human variation in the eighteenth and nineteenth centuries, including Georges Buffon (1707–1788, who published Varieties of the Human Species in 1749), Jean-Baptiste Lamarck (1744–1829), and Georges Cuvier (1769–1832). Johann Friedrich Blumenbach (1752–1840) is often considered the founder of physical anthropology. Inspired by Linnaeus, Blumenbach was interested in documenting the anatomical differences among humans, establishing the field of comparative anatomy to do so. He published On the Natural Variety of Mankind in 1795, in which he proposed five distinct races.

Blumenbach’s grouping became the basis of the scientific classification system for race, which was developed and expanded in the nineteenth and twentieth centuries. But, as Darwin pointed out in The Descent of Man, race is a slippery concept. The number of races catalogued in Darwin’s day alone ranged from two to sixty-three. In modern time, race as a useful biological concept is largely considered by anthropologists to be without scientific merit. By any biological measure, even human groups long isolated geographically are more similar than they are different. Yet race is an issue that will not go away because the concept of race is as much political and social as it is biological.

Although in the twenty-first century biological anthropology is thoroughly grounded in the study of human diversity, nineteenth century biological (physical) anthropologists were preoccupied with such questions as whether humans were part of the natural world, or more than one species. Darwin’s theory of evolution, first published in 1859 in The Origin of Species, gave biological anthropology a conceptual framework. Old questions were immediately resolvable; evolutionary theory confirms that humans are part of the natural world and share a common origin with every other species on Earth. Other questions were not resolvable. For example, the question of how many species humans comprise became a question of how many races, and this question preoccupied anthropologists, along with human geneticists, for decades.

Homo sapiens (modern human) is the only surviving species of those that comprised the 1.5 to 2.5 million year old Homo lineage. Paleontologists still debate what extinct species should be considered Homo (based on fossil evidence), or the extent to which there were contemporary Homo species alive during the approximately 2 million years of hominid history. If Homo sapiens and Homo neanderthalensis (a Homo species, commonly known as Neanderthal, that lived in Europe and parts of western Asia from about 130,000 to 24,000 years ago, now extinct) were contemporaneous 30,000 and more years ago, for example, did they interbreed? Some anthropologists believe that the tools of modern molecular genetics may help answer this question. The 2003 finding of 12,000-year-old fossils of apparently small people in a cave on the Indonesian island of Flores, Homo floresiensis...
Man of Flores), raises the question of whether other Homo species were alive until even more recently than Neanderthals. This issue will be debated in the months to come. Whatever the question of interest to contemporary biological anthropologists, from comparisons between species to the origins of human traits, biological anthropologists will continue to couch questions within the framework of evolutionary theory.

Anne Buchanan

ANTHROPOLOGY, BRITISH
A. R. Radcliffe-Brown once said that anthropology has two beginnings: the first in 1748 and the second around 1870. For British anthropology, one could add a third beginning, around 1922, when both Radcliffe-Brown and Bronislaw Malinowski began teaching in earnest and published their major field monographs. Radcliffe-Brown’s first date, 1748, marks the first publication, in French, of Montesquieu’s Spirit of the Laws. Within two years an English edition appeared, and this greatly influenced the anthropological ideas of Scottish writers such as Adam Smith. His anthropological approach, modeled on Montesquieu’s, became known as “conjectural history.” The idea was that speculation and logical deduction, often supplemented by knowledge from early ethnographic reports, should lead us to understand the early history of society.

Institutional anthropology in Britain began in 1843 with the founding of the Ethnological Society of London, which merged with a rival society in 1871 to become the Anthropological Institute. Major publications around that time include Sir Henry Maine’s Ancient Law (published in 1861), J. F. McLennan’s Primitive Marriage (1865), and Sir Edward Tylor’s Primitive Culture (1871). Maine’s book overturned the Enlightenment notion of the “social contract” in favor of the family as the basis of society, and it also created the study of kinship as the central interest of the British tradition. One early debate centered on which came first, patrilineal or matrilineal descent? Maine favored the former, while McLennan favored the latter. Tylor’s contribution included his famous definition of culture as “that complex whole which includes knowledge, belief, art, morals, law, custom, and any other capabilities and habits acquired by man as a member of society” ([1871] 1958, p. 1).

Polish immigrant Bronislaw Malinowski began teaching at the London School of Economics in 1922, the year of publication of his Argonauts of the Western Pacific. That book describes the inhabitants of the Trobriand Islands, where Malinowski spent World War I and where he created the modern style of anthropological fieldwork (working in the native language and through participating in as well as observing daily activities of the people). Meanwhile, Radcliffe-Brown had the year before obtained a professorship at the University of Cape Town. He later moved to Sydney and to Chicago before returning to Britain to take a chair at Oxford University. His major monograph, also published in 1922, was The Andaman Islanders. Together Malinowski and Radcliffe-Brown came to emphasize contemporary society over social evolution. Malinowski called this new approach “functionalism,” and the idea was to see how each aspect of society related to other aspects. Radcliffe-Brown shied away from the word, but what others called his “structural-functionalism” emphasized further the relations between institutions in social systems, the classic four systems being kinship, politics, economics, and religion. He published his collected essays as Structure and Function in Primitive Society in 1952, and his theoretical approach (borrowed partly from Émile Durkheim’s sociology) together with Malinowski’s fieldwork methods became the twin hallmarks of the British tradition. These two men trained the first generation of professional anthropologists (most of the earlier ones having been amateur scholars), and established British anthropology as a great world tradition and the idea of the departmental seminar as the main means of teaching graduate students.
The United Kingdom became the world’s most expansive imperial power in the nineteenth century, and British anthropologists through the first half of the twentieth century took advantage of this. The Malinowskian emphasis on fieldwork encouraged interaction between indigenous populations of the empire and anthropologists, and also between anthropologists and colonial officials. Some of the latter even studied anthropology in British or Commonwealth institutions, and indeed, so too did some residents of the colonies, most famously Jomo Kenyatta, later the first president of Kenya, who did his PhD under Malinowski in the 1930s.

From the 1950s other influences came in. Max Gluckman, from South Africa, and other members of the “Manchester school” that he founded, introduced an interest in conflict and dispute settlement. Fredrik Barth, a Norwegian who studied at Cambridge University, emphasized individual action and fluent group boundaries over rigid social structures. Radcliffe-Brown’s successor at Oxford, Sir Edward Evans-Pritchard, pushed against functionalism from another angle. He came to see anthropology as more like the art of history-writing than like the practice of the biological sciences (Radcliffe-Brown’s favorite analogy was “society is like an organism”). Especially in his study of the religion of the Nuer of Sudan, Evans-Pritchard argued that anthropologists should aim to understand things such as religious belief from the native point of view and “interpret” them so they can be understood in one’s own culture.

British followers of the French structuralist Claude Lévi-Strauss became prominent in the 1960s, especially Sir Edmund Leach. In Political Systems of Highland Burma (1954), Leach argued that the Kachin he had lived with before and during World War II exhibited two forms of social organization, one being egalitarian and the other hierarchical. Groups oscillated between the two according to ecological influences, and the political structure too was apparent in the ways in which lineages were related through marriages. Leach, along with Rodney Needham, took to Lévi-Strauss’s “alliance theory” in kinship, and the great battle of the 1960s was between this idea (stressing relations between groups through marriage) and “descent theory” (the older British approach stressing the importance of descent groups). The 1970s saw battles within the alliance theory camp, with Needham and most other British alliance theorists looking to reflect accurately ethnographic realities of what they called “prescriptive” systems of alliance (where one must marry someone of a particular category of kin), whereas French thinkers tended to prefer idealized models far removed from ethnography.

In the 1970s Marxism became a dominant force, with work such as that of Talal Asad critiquing relations that had existed between colonialism and the development of British anthropology. Other British-based anthropologists, including Maurice Bloch, Jonathan Friedman, and Joel Kahn, argued for greater awareness of historical global influences such as colonialism and capitalism on the populations anthropologists work with. Through the 1980s and 1990s the influence of American anthropology further watered down classic British interests, and today there is little difference, except in the way the history of the discipline is construed, between British anthropology and other traditions. That said, British anthropology retains particular strengths in studies of conflict, social development, and kinship (including new reproductive technologies), as well as in ethnographic writing. It also retains strong pedagogical elements from its earlier times, notably the tradition of departmental seminar as a means of teaching and of debate.

ANTHROPOLOGY, LINGUISTIC

Linguistic anthropology examines the links between language and culture, including how language relates to thought, social action, identity, and power relations. It is one of the four traditional subfields of American anthropology, sharing with sociocultural anthropology its aims of explaining social and cultural phenomena, with biological anthropology its concern over language origins and evolution, and with archaeology the goal of understanding cultural histories. Linguistic anthropology has developed through international work across social science disciplines, as researchers attend to language as a key to understanding social phenomena. The discipline overlaps most closely with the sociolinguistic subfield of linguistics. But while sociolinguistics generally considers social factors in order to explain linguistic phenomena, linguistic anthropology aims to explain social and cultural phenomena by considering linguistic information.

Linguistic anthropology, as a part of American anthropology, has its origins in the work of Franz Boas's 1911 Handbook of American Indian Languages. Inspired by his work with Native American groups, Boas introduced the concept of linguistic and cultural relativism, the premise that a particular language or culture can only be understood with regard to its own internal logic. The concept of linguistic relativism was developed further by Edward Sapir and Benjamin Whorf, who argued that languages predispose the speakers to experience the world in particular ways. This axiom has come to be known as the "Sapir-Whorf hypothesis." Researchers have since explored the extent to which language shapes thought, for example, with studies of color terminologies. These trends led to "ethnoscience," a field of research founded in the 1960s that focused on the systematic ways of understanding the world that are encoded in language. This approach was strongly influenced by the work of Swiss linguist Ferdinand de Saussure, whose analysis of language as an idealized social system set the foundations for the structuralist approach in anthropology. Recognizing the unique value of every language, linguistic anthropologists continue to document the grammars, cognitive maps, and traditional knowledge of threatened cultures and their languages in an effort to preserve and revitalize them.

The interest in language as a window on thought was paralleled by an interest in language as a means of acting upon the world. This line of inquiry drew on the work of philosophers John Austin and John Searle. They examined the performative function of language in speech acts (called performativity), actions that are accomplished as words are spoken, such as promising and marrying. Linguistic anthropologists extended the concept of performativity, viewing all language in use as a constructive activity and not just a means of relaying pre-existing information. Language is social action at many levels, from the construction of personality and beliefs, to the negotiation of social status between people, to the assertion of authority and group identities at the level of nations or transnational groups.

From analysis of contextualized speech acts, anthropologists John J. Gumperz and Dell Hymes introduced the ethnography of communication in the 1960s. This approach examines the rich cultural and contextual knowledge required to communicate competently, beyond knowledge of words and grammar. The speech community was proposed as a unit of analysis based on observed interactions, in place of pre-existing idealized categories. The ethnography of communication had much in common with the ethnomethodology approach developed in sociology starting in the 1960s by Harold Garfinkel and Erving Goffman. The methods of conversation analysis were elaborated by scholars in both anthropology and sociology, relying on analysis of recordings to uncover the rules governing interactions that usually function below the level of awareness (e.g., norms for turn-taking, timing, topic control, and other factors shaping social positioning). Linguistic anthropologists examine these interactional dynamics and rules across cultures and, among other things, seek to explain the reasons for cross-cultural miscommunication.

Discourse analysis expands from a focus on conversations to include analysis of language use in any context in both verbal and written form, including speeches, storytelling, ritual, performance, television, newspapers, and the Internet. Discourse analysis methods attend to both content and linguistic forms used (e.g., active or passive grammatical construction, inclusive or exclusive pronoun choice, formality of language) to show how linguistic forms affect people's thoughts, actions, and identities. In linguistic anthropology, a major concern in the analysis of discourse is how inequalities of power are created, expressed, and manipulated through language. Also of particular interest are processes of socialization (how children or adults learn new social rules) and how agency (an individual's ability to act) is expressed and enacted in speech. At the broadest level, analysis of discourse can also refer to examination of discourse as the systems of logic pervading a society (e.g., ways of thinking and talking about things, ways of arranging things in space) that shape social differences and power inequalities. This way of thinking about discourse was proposed by philosopher Michel Foucault.

The study of language as social action has also led to a view of language as a fluid, shifting, and heterogeneous medium, replacing Saussure's notion of languages and cultures as discrete idealized units. Influential in this develop-
ment was the work of Russian linguists Valentin Voloshinov (Marxism and the Philosophy of Language) and Mikhail Bakhtin (Discourse in the Novel), who theorized that language is “heteroglossic,” its meanings never fixed but always emerging anew between speakers, shaped by histories of social experiences, intentions, and desires. This approach posits language as the site of struggles over social power, supporting the analysis of the role of language in political economy. This area of research examines in part how authoritative and prestigious languages are constructed, how named languages and correlating national or ethnic units and identities are defined, and how language values are negotiated in multilingual situations. Beginning in the 1990s, interest in the relationships between language, power, and identity led to a focus on language ideology, the ideological link between linguistic forms (e.g., different languages, registers, or word choices) and social forms (ethnic, gendered, socioeconomic, or other social distinctions). Researchers studying these topics examine the meaning-making processes and stances through which people construct identities, taking into account both historical trajectories and contemporary contexts of language use.

While linguistic anthropology overlaps with many other fields in its topics of inquiry, its distinctiveness as a field lays in its holistic comparative cross-cultural approach and fieldwork-based research methods.

ANTHROPOLOGY, MEDICAL

Medical anthropology is the subdiscipline of anthropology that focuses on the intersection of health, medicine, society, and culture. Generally thought to include the study of the impact of disease on society and the impact of society and culture on health and disease, medical anthropology encompasses several different paradigms for research, including biocultural anthropology; ethnomedicine; social and cultural factors in the incidence, prevalence, and treatment of disease, or social epidemiology; the political economy of health; and the inclusion of cultural and social concerns in the planning, implementation, and evaluation of projects, which is the core of applied medical anthropology.

ORIGINS OF MEDICAL ANTHROPOLOGY

In 1978 George Foster and Barbara Anderson, following Khwaja Hassan (1975), suggested that the field of contemporary medical anthropology has four distinct roots that came together in the mid-twentieth century to form a recognized subfield of inquiry: the interest in variation in human morphology and paleopathology that began in the mid-nineteenth century, carried out in part by anatomists and early physical anthropologists; the culture and personality movement, or psychological anthropology, that began in the early twentieth century as an offshoot of and a critical alternative to Freudian psychology but gained strength during World War II because of increasing interest in understanding the psychological makeup of the different cultures involved in that conflict; the study of ethnomedicine, which began as part of ethnography in the nineteenth century but became a focus of study for culturally oriented medical anthropologists after the posthumous publication of W. H. R. Rivers’s Medicine, Magic, and Religion in 1924; and the
applied anthropology of public health, which arose from the post–World War II interest in improving health practices and introducing biomedicine in developing countries. The continuation of these themes can be seen in contemporary medical anthropology in the form of biocultural anthropology, ethnomedicine, critical medical anthropology (CMA), applied medical anthropology, and psychological anthropology.

**REVIEWS AND ORGANIZATIONS**

The first review that addressed the subfield was William Caudill's 1953 article "Applied Anthropology in Medicine." As the title suggests, it was a review of the inclusion of anthropological concepts and ethnographic methods in medical settings, or in medical sociologist Robert Straus's terms, social science in medicine (1957). The first review article with the title "Medical Anthropology" was published by Norman Scotch in 1963 and was more comprehensive in its approach. Subsequent reviews by Horacio Fabrega in 1971 and Anthony Colson and Karen Selby in 1974 continued to debate the nature of the field, with the latter article discussing whether medical anthropology constituted a subfield of anthropology or the intersection of anthropology and medicine.

By the mid-1970s, however, there was a well-organized association representing the field of medical anthropology that embraced the full range of work by people who called themselves medical anthropologists. The Society for Medical Anthropology (SMA) started as the Steering Committee for the Organization of Medical Anthropology, which began publication of the *Medical Anthropology Newsletter* (MAN) in 1968. MAN later became the *Medical Anthropology Quarterly* (MAQ). In 1987 MAQ achieved status as a peer-reviewed quarterly journal that publishes across the full range of research in medical anthropology.

**PHILOSOPHIES AND THEORIES**

Biocultural anthropology draws heavily on the work of the neoevolutionary theorists of the mid-twentieth century and the adaptation paradigm that entered medical anthropology in the 1970s after the publication in 1970 of Alexander Alland's *Adaptation in Cultural Anthropology: An Approach to Medical Anthropology*. It includes anthropologists trained in cultural anthropology and those trained in biological anthropology and generally examines the way in which adaptation to particular physical and social environmental conditions shapes the experience of disease and illness in societies and the ways in which society adapts to challenges presented by disease. It also involves researchers working in human biology, and early interest among physical anthropologists and anatomists in paleopathology is represented currently by forensic anthropology. Biocultural anthropology has been criticized by writers with a CMA perspective for its failure to assess the assumptions in the adaptation/neoevolutionary theoretical framework critically. However, current theorists such as Goodman and Leatherman (1998) and Andrea Wiley (2004) have attempted to include a political economy approach in biocultural anthropology.

Critical medical anthropology and the political economy of health approaches draw heavily on the work of Marxist and later poststructural social theorists such as Michel Foucault (1975). The central project of CMA is a critical examination of the assumptions and practice of biomedicine, their application in medicine and health policy, and the diffusion of biomedical understandings to non-Western settings, in Straus's terms, social science of medicine (or ethnomedical systems). Drawing on the work of Rudolf Virchow, it also can include the application of theory from political economy to the understanding of the distribution of health and illness. Key books in this area include the works of Paul Farmer (1999, 2003), Merrill Singer (2006a, 2006b), and Nancy Scheper-Hughes (1992) and more comprehensive works such as *Medical Anthropology in the World System* (Baer, Singer, and Susser 2003).

Applied medical anthropology has its roots in the international public health movement that gained momentum after World War II. One of the first series of studies of the role of ethnomedical beliefs in the adoption of public health practices and biomedical treatment was carried out by anthropologists working for the Smithsonian Institution's Bureau of American Ethnology under contract to the Office of Special Studies, which later became the U.S. Agency for International Development. Some of this work is summarized in *Health, Culture, and Community*, edited by Benjamin Paul (1955), which argued for the inclusion of the study of ethnomedical beliefs in the design and implementation of public health programs. A number of anthropologists have worked with bilateral and multilateral health organizations such as the U.S. Agency for International Development and the World Health Organization. Interest in the study of non-Western medical systems also has been incorporated, including Mark Nichter's work on ethnomedical systems and medical change (1989, 1992). The line dividing primarily theoretically oriented and primarily applied research has become blurred. Several critical theorists, such as Merrill Singer and Paul Farmer, are deeply involved in the design and implementation of interventions and use a political economy approach to understand the epidemiology of disease and illness.

ANTHROPOLOGY, PUBLIC

Public anthropology focuses the distinctive perspectives and methods of anthropology on public issues. Since the founding of anthropology as an academic discipline in the late nineteenth century, it has changed a great deal and divided into numerous specialties and schools of thought, but certain key features abide. Anthropology is comprehensive of space and time: it covers the entire world, and it treats humankind throughout its history and prehistory, including the present. It is also comprehensive in aspect, treating biological as well as cultural features of humans, and it tends to be holistic, considering how various aspects of life fit together rather than attending mainly to one aspect, such as economics or politics. Finally, anthropology relies strongly on fieldwork, whether archaeological excavation or participant observation of all manner of contemporary situations. Public anthropology deploys these characteristic approaches of anthropology to address public issues.

Some consider public anthropology to be an extension of an older field, applied anthropology, which is also termed practicing anthropology. That is a valid perspective, but public anthropology tends to focus less on specific problems than on the issues and policies that create the

Kathleen Musante DeWalt
problems. Applied anthropology, for example, might aid a community in correcting a problem with pollution, while public anthropology might address the policies or culture that create the pollution. Among those practicing and defining public anthropology, emphases and terminologies vary. Public interest anthropology, for example, emphasizes that the issues the field is concerned with are defined by public bodies’ interests (Sanday), while Rob Borofsky would include the publicizing of anthropology—connecting public figures and public arenas to anthropology.

Whereas anthropologists generally attempt to understand and appreciate all human behaviors, a public anthropologist may conclude that some behaviors or situations should change. She or he may judge that some actions violate human rights and move beyond cultural relativism to take a position against torture, child slavery, or the oppression of women, for example, and then work to prevent those actions or even to change the situations and culture that support them.

Moving from scholarly understanding to advocacy and action, public anthropology may modify classic methods. Ethnographic fieldwork is excellent for in-depth analysis but may take too long to be a good way of investigating urgent problems. Holism offers breadth but can distract attention from a problem at hand. Anthropology as a discipline offers much, but the work of addressing public issues cannot be confined to a single discipline. Instead, it requires a combination of academic disciplines and necessarily reaches beyond academics to involve the entire community. Researchers may need to engage with or even become leaders, administrators, and advocates. Public anthropology welcomes such disciplinary intersections and forms of engagement (Peacock 1997).

Historically and in the early twenty-first century, a variety of anthropological efforts illustrate possibilities for public anthropology, though they are not always labeled as such. Lee Baker’s account suggests that the founder Franz Boas’s efforts to combat racism were an early example of public anthropology. Boas utilized careful research to demonstrate, for example, that the shape of one’s head is influenced by the environment. From this, he argued against racism on the ground that the environment, including culture, is a major factor in shaping physical characteristics that many of his contemporaries identified as being specific to race. Boas’s student Margaret Mead (1928) followed his lead by demonstrating through her fieldwork in Samoa that adolescence is culturally shaped and not merely biologically determined. After completing fieldwork in New Guinea and Bali, Mead went on to apply anthropology to a range of public issues, one of which was gender. She utilized her fieldwork to show how definitions of male and female depend on cultural context, and hence she argued for a more flexible understanding and acceptance of wider variation in the roles of both women and men (Mead 1949).

Early twenty-first century examples of public anthropology are diverse. Paul Farmer, a physician and anthropologist, practiced in Haiti initially and addresses public-health issues globally (Kidder 2003). Johnnetta Cole is an anthropologist who has served as a college president, first of Spelman College and then of Bennett College—both historically black colleges for women that Cole has shaped into institutions that nurture positive values. Other examples range from James Peacock’s (2007) efforts to build international concerns at a state university and in a regional context to the creation of a union of academics and activists (CIRA) and investigation of public issues in communities (Holland et al. 2007).

Among formal anthropological organizations, public anthropologists can be found in the National Association of Practicing Anthropologists and the Society for Applied Anthropology and among the thirty-plus sections of the American Anthropological Association (identified by specialty or cultural/ethnic focus) as well as in the Royal Anthropological Institute and many international organizations. Several universities offer programs in public anthropology, and there are publications focused on the discipline. The work also occurs in interdisciplinary and nonacademic organizations ranging from local legislatures to international bodies, such as the United Nations.

Public anthropology, then, is not easily defined by pinpointing a single organizational affiliation or any certification; one is not certified to practice public anthropology. It is best recognized as an approach or practice that utilizes anthropological training, knowledge, and perspectives in addressing societal issues.

In a global and diverse world, issues require comprehensive perspectives. More so than most disciplines, anthropology is comprehensive, encompassing a century of field experience in diverse global contexts. The challenge for public anthropology is to deploy that experience in active engagement to address pressing issues effectively. On the one hand, public anthropology must broaden its vision beyond its British and North American academic origins as diverse cultures and communities assume leadership roles; on the other, it must hone its methods to make an impact.

Anthropology, Urban

Throughout history, cities have been important places of associated life, human diversity, and interaction. However, while twentieth-century sociologists have been at the forefront of urban studies, social and cultural anthropologists have long neglected the city as a relevant field of research. In the late 1930s a few anthropologists, such as Robert Redfield (1897–1958), shifted their attention from tribal and rural communities to peasant city-dwellers. Influenced by the Chicago school, some American anthropologists engaged in problem-centered studies that focused on poverty, ecology, and minorities; they developed such concepts as the “culture of poverty,” cited by Oscar Lewis in Five Families: Mexican Case Studies in the Culture of Poverty (1959). Many of these studies examined rural-urban migration in slums and shanty towns in Mexico and other Latin American countries. Meanwhile, a group of anthropologists led by the South African Max Gluckman at the Rhodes Livingston Institute of Northern Rhodesia studied the effects of urbanization on tribal economy and social relations, particularly in the Copperbelt area of central Africa. Research in African cities, however, was not really considered urban research, according to Ralph D. Grillo in Ideologies and Institutions in Urban France: The Representation of Immigrants (1985). Although such pioneering work was later criticized for its functionalist approach, it did contribute to the development of new anthropological methods, such as case and network analysis.

More generally, anthropologists seemed to consider the city a new laboratory in which to carry out traditional studies on kinship, small-group dynamics, and belief and value systems. This trend continued throughout the 1960s, prompting Ulf Hannerz in Exploring the City; Inquiries toward an Urban Anthropology (1980) to question whether urban anthropology had a specific subject of study.

A more eclectic and regionally diversified urban anthropology emerged during the 1970s as field research was conducted in Japan, India, and Indonesia, and across Africa and South America. Such socioeconomic and geopolitical variety raised some confusion in precisely defining the term urban. For some, urban referred to population aggregates of a certain size. Others defined urban in terms of occupations other than agricultural or subsistence production. Still others defined urban as the density of social interaction rather than just demographic or physical density. From a Marxist perspective, it was argued that class struggle constituted the essence of urban life. Two main positions eventually emerged. One regarded the city as a totality that should be studied in itself. The other argued that the city could not be studied as an isolated unit separated from the wider national and international context. Richard G. Fox in Urban Anthropology: Cities in Their Cultural Setting (1977) expanded on this position by including historical analysis in the locally significant global context.

By the early 1980s anthropologists appeared to be divided between those who focused on so-called third-world societies—continuing to address town-country relations, rural migration, and urban adaptation—and those with an interest in industrial societies. The latter were mainly native anthropologists.
In Euro-American societies, urban anthropology grew in parallel to the study of the anthropologist’s own society. However, many European anthropologists, especially in Britain, regarded the study of one’s own society as not “distant” enough to be fit for anthropological research. In contrast, American anthropologists had a long tradition of domestic interest. Their so-called exotic subjects were American Indians, urban migrants, and immigrant ethnic communities. Hannerz, who had carried out a pioneering study of “ghetto” culture and community in *Soulside* (1969), later criticized this approach for viewing the city as a mosaic in which each piece presented different problems. In his later work, *Exploring the City* (1980), he saw the failure to bring together the various pieces as a major limitation of earlier urban research. Criticism aside, American anthropologists such as Ida Susser (1982) and Leith Mullings (1997) have produced in-depth analyses on such issues as urban poverty, ethnicity, and gender.

**RELUCTANCE TURNED TO NEW METHODS**

Anthropologists’ reluctance to engage in urban research originated in the fear of losing their disciplinary identity and in the view that the disciplinary paradigm, which had been developed for the study of village and tribal communities, could not be applied to larger, more complex communities. This debate developed into an advocacy for new methods.

While urban geographers such as Doreen Massey (1999) and sociologists such as Herbert J. Gans (1967) have become increasingly interested in the ethnographic methodology, anthropologists such as Sandra Wallman have doubted the applicability of participant observation in metropolitan areas. In her research in East London, published in *Eight London Households* (1984), Wallman applied research methods borrowed from other disciplines, calling it “anthropology by proxy.” In contrast, Italo Pardo’s research in Naples in the mid-1980s, presented in *Managing Existence in Naples* (1996), eminently proved that not only was participant observation possible, but that a holistic study in the anthropological tradition could productively be done in urban Europe. Key points of Pardo’s work are a focus on the agency-system relationship, on the link between micro- and macro-level analysis, and on the sociological relevance of “strong continuous interaction” (Pardo 1996, pp. 11–12) between the material and the nonmaterial in people’s rational choices. New urban research followed, including that of Giuliana B. Prato (2000), on the interactions among economic, political, and cultural aspects of urban life, which contextualized local dynamics and change in national historical processes. Later works, such as that of Manos Spyridakis (2006), have used such an approach to examine the relationships between local and national processes and global restructuring.

The diversity of the societies studied by anthropologists inevitably led to different forms of urban anthropology worldwide. In the 1980s a new trend emerged in the United States. Apart from studying the poor, the marginal, and ethnic minorities, anthropologists began to examine such topics as inherited wealth, congressional patronage, and transnational migrants. Ethnographies on African societies moved to new grounds, examining the dramaturgy of power and status symbolism, the economic role of women, informal activities, ethnic conflict, the reemergence of witchcraft, and new urban segregation. Work, class, gender, religion, and bureaucracy, along with urban planning, became major topics of urban research in Asia. Many urban ethnographies on Latin America focused on economic policies, local politics, women’s work, urban development and planning, and indigenous rights.

Urban research in Europe appeared more geographically diversified in the early years of the twenty-first century. Sweden was at the forefront of urban research, addressing welfare institutions, class, and culture in relation to ethnicity. In Britain, apart from a few exceptions, urban research mainly focused on ethnic groups from Commonwealth countries. Urban France attracted the attention of both British and native anthropologists. In spite of a slow start, more urban research was carried out in southern and eastern Europe.

The fields of study mentioned thus far are by no means exhaustive of urban anthropological research. They represent major trends that have developed over the years. Throughout the 1990s, new developments in urban anthropology—notably those of Pardo (2000, 2004)—have investigated the relationships among elite groups, those between ordinary people and the ruling elite, and the legitimacy of governance. In the early twenty-first century—marked by transnationalism, globalization, the reemergence of localism, and the project of multiculturalism—this trend addressed the urgent need to understand the city as a crucial arena in which citizenship, democracy, and, by extension, belonging are critically renegotiated and the morality of law and politics are increasingly questioned and scrutinized.

Some trace the concept of anthropology, an academic discipline devoted to understanding every aspect of humans and their societies, to the Greek culture from which its name, anthropos (human being) and logos (knowledge), derives. According to Merwyn S. Garbarino in Sociocultural Theory in Anthropology: A Short History (1983), it is the breadth of anthropology’s coverage, and its ability to combine the categories and interests of other fields like economics, political science, social psychology, sociology and even biology that brands it as unique—a holistic approach to “the study of …[humankind] the animal and …[humankind] the social being through time and space” (Garbarino 1983, p. 2).

ORIGINS

Anthropology is very much rooted in European intellectual traditions (Herodotus’s descriptions of other societies in the fifth century BCE), Europe’s expansion as a colonial power (Marco Polo’s ethnographic details of the court of Kubla Khan in Peking around 1275), and the rise of imperialism. The Enlightenment was a time of profound and systematic inquiry into the nature of humans (cast during that time as the nature of man), and the ideas of Enlightenment scholars shaped many of the core questions that still direct anthropology in the early-twenty-first century. Building upon the approaches of natural history, the precursor to what is now called science, scholars like Jean Jacques Rousseau, Thomas Hobbes, and John Locke attempted to explain human social and cultural variation...
by seeking to uncover the natural laws that governed the rational order of the universe. The logic behind Newton's *Principia Mathematica* and Locke's *Essay Concerning Human Understanding*, two of the most influential works of the time, could best be summarized as follows: “The universe was rationally ordered, and laws could be discovered that explained the motions of the planets and the behavior of people” (Garbarino 1983, p. 12, emphasis original). These principles were thought to be the key to answering two questions about humans as social creatures and human cultural and biological variation: “Why do people behave the way they do?” and “What causes human diversity?” The theories developed in anthropology were attempts to answer these two questions about human behavior and observable differences in societies and in human phenotypes using natural science methodology.

Colonial contact with non-complex, non-industrial other societies gave Europeans the understanding that such societies were *primitive* because they did not mimic European society. By the nineteenth century, social theorists, like anthropologists, adhered to a “doctrine of progress,” according to editors W. L. Partridge and E. M. Eddy in *Applied Anthropology in America* (1978). As they described it, “Throughout centuries of progress, the modern, ‘superior,’ ‘moral,’ social life of nineteenth century industrialism was believed to have developed from ‘primitive,’ ‘immoral,’ ‘childlike’ societies” (p. 7). Anthropologists believed that by studying such societies, one could trace the progress from so-called primitive societies to their own contemporary status, always holding European social development as the ideal. The two theoretical camps that emerged in the mid-nineteenth century were those who interpreted non-western societies through a lens of *unilinealism*, and argued that “all societies passed through a single evolutionary process,” and those who professed a belief in diffusionism, an attempt to explain “the spread of a cultural item from its place of origin to other places” (King and Wright 2003).

Underpinning these theories, and many of the other ideas that would shape anthropology, was the belief in cultural evolution, led by Herbert Spencer. He believed “evolution to be one of the fundamental processes in the universe” (McGee and Warms 2000, p. 7). Charles Darwin also cited Spencer's work in his theory on biological evolution. At the close of the nineteenth century, Europeans dominated the development of anthropological theories and practices: from Lewis Henry Morgan (1818–1881) and Edward Burnett Tylor (1832–1917) to Sir James Fraser (1854–1941); Karl Marx, whom Garbarino argues did not do “competent anthropology” (Garbarino 1983, p. 39); his collaborator and benefactor, Friedrich Engels; and Émile Durkheim.

Some of these great theorists, such as Fraser and Tylor, had never conducted field research, drawing their generalizations from the ethnographies of anthropologists who conducted ethnographic fieldwork as well as from the nonscholarly observations and descriptions of missionaries and travelers. In England and France, sociocultural anthropologists remained separate from those studying archaeology and physical anthropology, and colonialism, fueled by theories of unilineal evolutionism, further reinforced ethnocentric views that so-called primitive societies were at a lower scale of development than those in Europe. Durkheim's use of the cross-cultural approach to understand “social development, suicide, religion, and above all, social cohesion,” moved French sociology into the realm of anthropology, and Durkheim is claimed by the discipline today as a key figure (Garbarino 1983, p. 38).

**THE EMERGENCE OF AMERICAN CULTURAL ANTHROPOLOGY**

Cross-cultural comparison, the culture concept, cultural relativism (introduced by Charles Louis de Secondat, Baron de la Brede and de Montesquieu [1689–1755], generally referred to as Montesquieu), the professionalization of data collection (including William H. R. Rivers's genealogical method used to trace descent and describe kinship patterns as a window onto understanding general social relations), and critiques of unilineal evolutionist approaches to explaining sociocultural variation were all part of the emerging field of anthropology. Also part of it was a belief among “British and American anthropologists … that good ethnographic information would help government personnel avoid mistakes that might be not only costly but also painful and destructive to native peoples” (Garbarino 1983, p. 44). This cozy relationship between colonial administrators and anthropology, such as the Royal Anthropological Institute’s training center for colonial administrators, would come back at the end of the century to haunt anthropology, produce a distrust between former colonial people and the discipline in the so-called Third World or the Global South, and give anthropology the unfortunate, but accurate for the period in question, moniker—“child of imperialism and colonialism” (Garbarino 1983, p. 44).

In the United States, at the American Museum of Natural History, a transplanted German, Franz Boas, embarked on the Jesup North Pacific Expedition (1897–1902). The data he collected affirmed the value of anthropologists doing their own research rather than relying on the reports of others. “He encouraged his students to collect as many ethnographic data as possible—total recovery was his goal” (Garbarino 1983, p. 48). Boas turned his back on the tendencies prevalent in the disci-
pline: sweeping and broad generalizations and comparisons. Rather, he stressed to his students that they accumulate large bodies of data using a holistic approach before venturing toward any conclusions. What set Boas apart from his peers was that “while evolutionists had searched for similarities, …[he] looked for diversity.” He also paid close attention to history, “believing that each society could be understood only in light of its particular past” (Garbarino 1983, p. 48). In his 1920 essay, “The Methods of Ethnology,” Boas summed up his critique of the flawed logic of both evolutionism and diffusionism in the following way: “These methods are essentially forms of classification of the static phenomena of culture according to two distinct principles, and interpretations of these classifications as of historical significance, without, however any attempt to prove that this interpretation is justified” (Boas 2000, p. 135).

According to McGee and Warm's discussion of Boas in their history of anthropological theory, Boas “pioneered the concept of cultural relativism in anthropology.” Further, his approach of historical particularism emphasized the discipline's holism, and drew upon the study of “prehistory, linguistics, and physical anthropology” (McGee and Warms 2000, p.131). Boas's desire to introduce scientific rigor to this emerging academic field and his quest for holism were directly responsible for academic American anthropology acquiring the four-field signature of cultural (social) anthropology, archaeology (or prehistory), biological (or physical) anthropology, and linguistics anthropology (Miller 2004, p. 2). This holistic approach would distinguish American anthropology, going forward, from its European progenitors. Boas also brought to this emerging discipline a new “agenda for social reform” as well as theories of race that challenged the prevailing status quo beliefs. He believed that environment and nurturing were significant factors in human development. In his 1940 essay, “Anthropological Study of Children,” Boas noted, “Some observations have been made that illustrate the influence of environment, not only upon growth of the bulk of the body but also upon some of the forms that develop very early in life” (Boas 1982, p. 101). Boas's students were the first generation of formally trained academic American anthropologists, and many would become leading figures in the discipline—Alfred Kroeber, Robert Lowie, Edward Sapir, and Ruth Benedict. Subsequent students included Margaret Mead and Zora Neale Hurston.

American anthropology continues to embrace holism, and although the four-field approach, the culture concept, and cultural relativism have drawn sharp criticism and debate, they remain cornerstones of the discipline's distinctiveness. American anthropology's history of contributing to social reform has also attracted new thinkers that include women, nonwhite, and gay, lesbian, bisexual, and transgendered anthropologists. Their contributions include ongoing interrogations of evolutionist theories, positivism, modernization, critiques of ethnocentrism, homophobia, sexism, and racism, both in the society and within the academy, and challenges to the scientific validity of the concept of race, while acknowledging the power of social race. Their interpretive approaches and use of identity politics support methodologies quite different from the empiricism that H. Russell Bernard (1998) claims is ubiquitous to the discipline. These characteristics, along with the persistence of the four-field approach, and a long-standing tension between humanism and science, continue to distinguish American anthropology from its British and French cousins.

ANTICOLONIAL MOVEMENTS

During the eighteenth and nineteenth centuries the states of western Europe projected their power and their rivalries into much of Asia and Africa, establishing an “era of western domination over the rest of mankind” (Emerson 1960, p. 5). This creation of a global imperial order eventually generated a counterrevolution as colonized peoples organized anticolonial movements that asserted their rights to self-government. The age of imperialism spawned an era of nonwestern nationalism that gained great momentum during the twentieth-century world wars, thus changing the face of contemporary international politics.

The competition to acquire overseas territories was fueled by political, economic, and technological factors. European states developed military technologies, including naval maneuverability and enhanced firepower, that allowed them to prevail over the societies they sought to conquer. The search for exotic goods, raw materials, and new markets in which to trade provided a material motive for expansion. Political prestige was at stake as well, as states sometimes sought to compensate for defeats in Europe by victories abroad; doctrines such as the “civilizing mission” were invented to justify colonial empires. This gigantic historical enterprise transformed Asia and Africa, not the least by unleashing the will of the colonized to strike back.

Anticolonial movements such as the Indian National Congress, the Association of Vietnamese Revolutionary Youth, and the United Gold Coast Convention took form in individual colonies to confront different local situations. These diverse local movements were well aware of one another, prompting a transnational sentiment of solidarity against colonial rule. Although each movement adopted its own tactics and strategy according to its local circumstances, they shared a sense of common cause with one another. Some struggles for independence were violent, others primarily diplomatic, and yet other anticolonial forces shrewdly combined political and military means to achieve their goals.

A representative regional example of these historical processes can be seen in the case of North Africa. In 1830 France invaded the territory of Algeria, waging an extremely bloody war of conquest. Finally overcoming prolonged Algerian resistance, the French colonial administration encouraged European settlers to occupy the country. Once established in Algeria, France extended its power by imposing protectorates over Tunisia (in 1881) and much of Morocco (in 1912). Then as World War I (1914–1918) engulfed Europe, the French conscripted North African manpower into its army. When these soldiers returned from the trenches of Europe, they contributed to laying the early groundwork for what became national movements for independence. World War II (1939–1945) further eroded the foundations of empire as another generation of Africans was enlisted in the French war effort. In Algeria the National Liberation Front (FLN) took up arms in 1954, spurring France to negotiate the independence of neighboring Tunisia and Morocco in 1956. Through effective diplomacy as well as armed resistance, the FLN achieved the independence of their nation in 1962.

Movements such as Algeria’s FLN emerged, often under the leadership of western-trained elites, throughout the colonized world. Mahatma Mohandas Gandhi and Jawaharlal Nehru mobilized the Indian people against the inherent inequalities of colonial rule in the name of certain liberal principles such as self-determination, as articulated by the U.S. president Woodrow Wilson. The Vietnamese nationalist Ho Chi Minh was inspired by both the U.S. Declaration of Independence and the anti-imperialist ideology of V. I. Lenin. Ho traveled to France and the Soviet Union on his path to organizing the anticolonial movement in Indochina. Kwame Nkrumah of Ghana studied in the United States, where he was influenced by pan-Africanism, another anticolonial doctrine. The Sorbonne trained the Tunisian lawyer Habib Bourguiba (1903–2000), who assumed the leadership of the nationalist Neo-Destour Party. East African leaders such as Jomo Kenyatta and Julius Nyerere studied in British universities. These intellectuals from developing countries found the means to turn the west’s rhetorical ideals of justice and democracy into tools of liberation. Thus did the imperial powers plant the seeds of the eventual formation of anticolonial movements.

Not only European wars, but also Asian ones destabilized the imperial order, allowing room for anticolonial movements to consolidate. Japan’s ambitions to become an imperial power in China in the 1930s, and later in Southeast Asia, shook the hold of the French in Indochina, the Dutch in Indonesia, and the British in South Asia. In India, where the Indian National Congress had been created as early as 1885 as a primarily elite organization, the anticolonial forces had built a mass movement incorporating a wide range of social groups by the 1920s. Thus the Congress Party was well situated to play a vanguard role in the march to independence in 1947. Nehru declared a neutralist foreign policy that offered support to other anticolonial movements. In rapid succession, Burma (now Myanmar) and Indonesia achieved independence under their prewar nationalist leaders—U Nu (1907–1995), who founded the leftist University Students’ Union in the 1930s, and Ahmed Sukarno (1901–1970), who formed the Indonesian National Unity Party in 1927. In Indochina, however, the French chose to resist the anticolonial League for...
Vietnamese Independence (or “Vietminh,” as Ho’s organization was known after 1941). France waged a costly war that lasted until the Vietnamese victory at Dien Bien Phu in May 1954.

The struggle in Vietnam was closely watched by the Algerian nationalists. The anticolonial movement in Algeria had long been divided into competing political parties and religious associations. The model provided by Vietnam’s successful guerrilla war inspired the more radical wing of the Algerian movement to organize the FLN, which carried out its first military operation on November 1, 1954, just months after the fall of Dien Bien Phu. Thus did a common anticolonialism lead to common strategy across colonized continents. The Algerian war in turn became a major episode in the history of decolonization. The FLN mounted an exceptionally dynamic diplomacy in the Arab world, Africa, and Asia, enlisting both recently independent governments and sub-Saharan anticolonial political parties in support of Algerian independence in such forums as the United Nations and the Bandung Conference. The latter, held in Indonesia in April 1955, was a meeting of the independent states of Asia and Africa, most of which were former colonies. The conference both celebrated this newly won independence and issued a call for ongoing efforts to end colonialism. The “spirit of Bandung” became a major mobilizational theme for the continuing anticolonial movement. The FLN was an unofficial participant in the conference (its representatives lodged within the Egyptian delegation) and it subsequently insisted upon representation of national liberation movements in similar conferences.

The pressure exerted upon the government of France by the war in Algeria became an asset for anticolonial movements in sub-Saharan Africa, speeding the process of decolonization on the continent. Likewise, the radicalization of the anticolonial movement in Ghana under Nkrumah—who proceeded from organizing the Fifth Pan-African Conference in England in 1945 to editing a paper called The New African in 1946 to serving as general secretary of the United Gold Coast Convention (UGCC) in his homeland in 1947—accelerated the pace of events. Disillusioned by the moderation of the UGCC, Nkrumah formed the Convention People’s Party in 1949 and promptly initiated a Gandhi-style campaign called “Positive Action,” for which he was imprisoned by the colonial authorities. His popularity obliged the British to deal with his movement; by 1954 he won a promise of self-government, by 1957 Ghana was independent, and in 1958 he convened in Accra an All-African People’s Conference, which was attended by anticolonial forces from around the continent. Meanwhile, Ahmed Sékou Touré (1922–1984), a trade unionist who had assumed leadership of the Democratic Party of Guinea in 1952, persuaded his compatriots to vote for independence from France in a 1958 referendum organized by French president Charles de Gaulle in his attempt to diffuse the mounting international opposition to the French war in Algeria. Political momentum arising out of this Algiers–Accra–Conakry axis enabled anticolonial forces to sweep away the fractured colonial framework in seventeen more African countries in 1960, the “year of Africa.”

The influx of former colonies into the United Nations General Assembly allowed the anticolonial movement to harness that institution to the goal of eradicating the final vestiges of colonialism. The assembly sponsored the passage of, for example, Resolution 1514, the Declaration on the Granting of Independence to Colonial Countries and Peoples (December 1960). They formed new instruments such as the Nonaligned Movement and the Organization of African Unity to pursue the remaining agenda of decolonization in the Portuguese colonies and the settler states of southern Africa. Activist states such as Algeria supported the training of guerrilla movements in Angola, Mozambique, and Portuguese Guinea; upon independence in 1975 the Frelimo government in Mozambique in turn aided the Patriotic Front in Southern Rhodesia (now Zimbabwe) and the African National Congress in South Africa, whereas Angola assisted the Southwest African People’s Organization (SWAPO) in Namibia. In South Africa, whose African National Congress (ANC, organized in 1912) was one of the oldest members of the collective anticolonial movement, the release of the activist leader Nelson Mandela in 1990 led to the election of an ANC government in 1994. These were among the final battles in the long march of decolonization.

The historian Hugh Tinker has called anticolonial militants “fighters, dreamers, and schemers.” Their common scheme was to build a local organization that could join a larger movement that restored self-rule to their peoples.

ANTI-SEMITISM

Is anti-Semitism a new name for an ancient, uninterrupted phenomenon? It is a recent name, no doubt—its 1878 coinage being attributed to Swiss radical Wilhelm Marr. Yet, new names have become one of the curious features of problems that either refer to a long and obstinate history (e.g., the hatred of the Jews through the centuries) or indicate sites of resistance, the refusal to confront diverse and changing phenomena. Understandably, different interests seeking to isolate and refute or, alternatively, contextualize “anti-Semitism” necessarily run the risk of sacralizing or banalizing it. Thus, inseparable from the study and elusive comprehension of such an object (or objects), the politics of anti-Semitism have involved most manifestly the definition of the word Semite (along with its companion, Aryan, a term that was invented in German Protestant theological circles circa 1771 and quickly spread to England, France, and their respective empires) and most covertly the very representation of the West vis-à-vis its others.

HISTORY

Scholars and ideologues differ in invoking, for different periods and regions of the world, terms such as Jew-hatred, anti-Judaism, Judeophobia, more recently including even anti-Zionism. Is there, then, one history of anti-Semitism through the ages (Almog 1988)? Should one not attend instead to the distinct histories of relations between Jews and the populations among whom they have lived? A further claim has been made that some forms of anti-Semitism have thrived, in fact, in the complete absence of Jews. French philosopher Jean-Paul Sartre, for example, famously asserted that anti-Semitism is essentially independent of the Jews, that it rather “makes the Jew” (“c’est l’antisémite qui fait le Juif”) (1948, p. 84). Indeed, it now seems as if anti-Semitism has become a unified and universal, indeed global, phenomenon, one that has spread and radiated from its historical center in early Christian theology (borrowing from earlier Greek and Latin writers) and in western Europe to all corners of the planet. When considering the genocidal paroxysm that hostility to Jews reached in Europe (and, incidentally, only there), the temptation has increased to read all prior hostility toward Jews as prefiguring the horrors of the Holocaust (Bernstein 1994).

EXPLANATIONS

Clearly, anti-Semitism demands explanation—and refutation—and many compelling cases have been made in this direction. Some have sought to testify to anti-Semitism’s quasi-eternal nature (Netanyahu 2001; Bein 1990) or account for its specific persistence (the recurrence of Christian theological prejudice). Others have explored vectors of change (the well-known, modern shift from religion to race described by Léon Poliakov; the teleological understanding of Daniel Goldhagen) and tried to account for historical distinctiveness (Amos Funkenstein on the changing and proximate nature of the Jewish-Christian dispute; Gavin Langmuir’s criterion of “socially significant chimerical hostility” [1990, p. 341]; Jeremy Cohen’s description of the medieval transformation of the Jews from “theological witness” to “demonic” figures) and geographical or cultural difference (Poliakov, again, as well as Mark Cohen). At times, Jewish thinkers themselves have gone so far as to consider Jewish “antisocial behavior” as a major source of anti-Jewish hostility (Bernard Lazare; Israel Yuval on Jewish collective suicide in the eleventh century).

Other reasons, equally contentious, have been proposed: materialist reasons, for example, and chief among them, socioeconomic ones (“Jews and money,” as the old topos goes, but see also Abram Léon’s notion of the Jews as a “people-class”), and political reasons (Karl Marx, but also Hannah Arendt’s theory of the modern state and the role of “political anti-Semitism” in it) and psychological reasons as well (Sigmund Freud on sibling rivalry and castration, and Max Horkheimer and Theodor Adorno on mimesis). Historians of science have shown the importance of new categories of thought and classification, including those operative in Jewish self-perception (Gilman 1986; Hart 2000). There are those who have sought to locate anti-Jewish hostility within the larger frame of attitudes toward “outsiders” (Mayer 1982) or as one among numerous features of a “persecuting society” (Moore 1987). A recurring dispute continues to separate those who wish to distinguish exclusionary practices on the basis of their (real or fantasmatic) targets and those who uphold the strategic usefulness of conducting a uni-
fied analysis of (and struggle against) all agents of exclusionary practices. Should all racisms be studied and fought as the different guises of one essence or should differences be acknowledged and exposed?

RECENT DEVELOPMENTS
Hannah Arendt (1958) insisted on the numerous elements and structures that relate attitudes toward the Jews with issues of state formation, modern racism, imperialism, and colonialism. After Arendt, however, the most significant breakthrough in the study of anti-Semitism was made by Edward W. Said (1978). Arguing that the history of Orientalism (and prominent among them “western views of Islam”) is the history of anti-Semitism, Said has enabled a novel understanding of the emergence of the category of “Semitics” as the most obvious manifestation of an enduring theologico-political problem. This problem, which antedates modernity, is at the heart of the West’s own constitution as a historical subject. Relating theological premises to political endeavors, and religion to race, Said demonstrates the necessity of understanding the distributive and dynamic distinctions between Jews and Arabs, between Judaism and Islam, strategically associating and dissociating the two from within the standpoint of Western Christendom and, later, of European colonialism (Anidjar 2003). This dynamic approach also means taking the measure of the late eighteenth-century invention of “Semites” as the unity of race and religion, of Jew and Arab (Olender 1992; Hess 2002). From this novel perspective, it becomes possible to better understand the spread of European anti-Semitism to the Arab world (described, for example, by Bernard Lewis and Geneviève Dermenjian), as well as phenomena like Zionism in its different figures, at once emancipatory and potential manifestations of covert self-hatred (Gilman 1986).

The intricate connections that tie modern anti-Semitism to Zionism may further explain the continued contaminations we witness today between the two (Wistrich 1990; Finkelstein 2005). The Zionist “negation of exile” also participated in the project to reinscribe and undo the unity of the Semites and recast it from within as either a separation of Jews from Arabs (anti-Semitism from Orientalism) or as a binational perspective—advocated by Martin Buber, Gershom Scholem, Arendt, and other members of Brit Shalom, a Jewish group founded in 1925 dedicated to promoting coexistence—seeking to invent and promote collective rights for both Jews and Arabs (Raz-Krakotzkin 2001). The debate over the persistence of anti-Semitism as anti-Zionism can therefore be better understood as the enduring effort to maintain Jews and Arabs as separate and opposed, indeed as objects of different, unrelated, exclusionary practices. Reframed as the unity of a theologico-political complex that manages both hostility to Jews and hostility to Arabs, anti-Judaism and the war on Islam, anti-Semitism and Orientalism, are revealed as indissociable: one and the same in their very difference.

ANTITRUST

Antitrust law—also called competition law—limits how competitors may act in the marketplace, unilaterally and especially collectively. The aim of antitrust law is to promote social welfare by protecting the competitive process. Two federal agencies are responsible for U.S. antitrust enforcement—the U.S. Department of Justice and the Federal Trade Commission. In addition, state attorneys general and private parties may bring antitrust suits to enjoin specific conduct or recover damages suffered as a result of antitrust violations.

One major antitrust law is the Sherman Act of 1890. It was the congressional response to the invention of the trust, a contractual coordination among competitors used to drive up prices. The U.S. Supreme Court developed two frameworks for applying Section 1 of the Sherman Act, which addresses anticompetitive agreements, including those forming trusts. The per se rule prohibits categories of agreements without consideration of their actual effects because they are inherently likely to eliminate competition without any offsetting social benefits. The most important of these categories are cartel agreements through which competitors fix prices, rig bids, or allocate customers. Cartels are prosecuted as felonies, and prosecution of international cartels since the mid-1990s resulted in many fines in excess of $100 million and imprisonment for many corporate executives. The rule of reason prohibits agreements in other categories if determined actually to harm competition.

Section 2 of the Sherman Act addresses unilateral conduct that would “monopolize” an industry. It has been applied sparingly, especially in recent decades. Landmark early cases resulted in the breakup of the American Tobacco Company and the Standard Oil Company. The most notable modern case involved Microsoft Corporation and resulted in a variety of prohibitions and requirements on its conduct.

The other major antitrust law is the Clayton Act of 1914, which contains several specific prohibitions, the most important of which applies to mergers that would substantially “lessen competition.” Since the 1970s, large mergers have been reviewed by federal agencies prior to consummation. The agencies file suit against roughly a dozen mergers per year, although all but a few are later consummated after the merging parties agree to divest significant assets. Controversial cases include the Justice Department’s unsuccessful challenge to Oracle Corporation’s takeover of PeopleSoft, and oil industry mergers the Federal Trade Commission allowed to proceed.

Antitrust law and policy have evolved considerably, especially as insights from economics were incorporated through case law development. At the vanguard was the Chicago School, which drew attention to efficiency reasons for business practices and was instrumental in limiting the application of the per se rule. Since the early 1980s, increasingly sophisticated economic analysis has been applied. The federal agencies and the courts rely on economic analysis in predicting the competitive effects of proposed mergers and assessing the effects of ongoing business practices.

Antitrust law was unique to the United States for a considerable time, but more than one hundred countries now have antitrust laws. These laws generally prohibit cartel activity, anticompetitive mergers, various specific business practices, and what is termed abuse of dominance. The prohibition of abuse of dominance is similar to Section 2 of the Sherman Act. International views on antitrust have converged a great deal, although complete convergence likely never will be achieved.

Outside cartel enforcement, debates on antitrust policy continue. Nearly all agree on basic goals of antitrust policy, but the best means to achieve those goals remain controversial. Recent debates have focused mainly on the proper standards for evaluating the potentially exclusionary conduct of a single competitor. Controversial practices
Antitrust Regulation

include 3M’s use of rebates across multiple product lines in sales to retailers (found unlawful in the United States) and Microsoft’s inclusion of its media player in its Windows PC operating system (found unlawful in Europe).

ANTITRUST REGULATION

Antitrust regulation is accomplished through legal statutes that proscribe anticompetitive conduct and unfair business practices. Its major role is to protect consumers against anticompetitive behavior that raises prices, reduces output, and hinders innovation and economic growth (Baker 2003). Antitrust laws originally were formulated for the purpose of combating business trusts. A trust was a legal form of business entity that was created during the nineteenth century in the United States in which the shareholders of the companies in an industry transferred their shares to a board of trustees in exchange for dividends. That process led to the formation of giant monopoly firms such as John D. Rockefeller’s Standard Oil Trust.

Eventually the term antitrust was used to refer to government regulation of monopolies in general.

IMPACT OF ANTITRUST REGULATION ON ECONOMIC ACTIVITY

The impact of antitrust regulation on the economy has been the subject of long-standing debate. Critics of the concept argue that excessive competition endangers the functioning of industries with high fixed costs and low marginal costs such as railroads and public utilities. In this case engaging in monopoly practices such as price discrimination may enable firms to recover fixed costs and realize economies of scale and scope (Kovacic and Shapiro 2000). There are also concerns about the way competition policy is designed and executed. Some corporate leaders feel that the laws are vague and ambiguous, whereas others think that antitrust statutes give too much power to politicians. Public choice theorists emphasize the idea that antitrust enforcement may not always serve consumers’ interest but instead favor private corporate or political interests.

Despite those criticisms competition generally is thought to be desirable for a variety of reasons: It stimulates individualism and innovation, guarantees wider product choices for consumers, and promotes economic efficiency as market participants strive for business success. Competition, however, cannot sustain itself. Without regulation competitors inevitably will agree to raise prices, and the victims of that conduct will be unable to protect themselves.

ANTITRUST REGULATION IN THE UNITED STATES

The first federal antitrust law in the United States, the Sherman Act, was passed by Congress in 1890. It outlawed “every contract, combination or conspiracy in restraint of trade” as well as “monopolization.” The legislation made illegal collusive arrangements such as price-fixing, bid rigging, resale price maintenance, and territorial and structural division agreements that would tend to establish a monopolistic practice. The Sherman Act gave federal judges substantial discretion in court, and that led Congress to pass in 1914 two other laws to substantiate the original statute: the Clayton Act and the Federal Trade Commission Act. The Clayton Act outlined particular practices that were deemed illegal, such as price discrimination (Section 2), exclusive dealing and tying contracts (Section 3), and corporate mergers when they were intended to create a monopoly (Section 7). The Federal Trade Commission Act formed an administrative body, the Federal Trade Commission, to design antitrust policy. Today the Federal Trade Commission and the
Antitrust Division of the Justice Department are jointly responsible for the enforcement of antitrust laws in the United States. In a 1993 article B. Dan Wood and James Anderson provided a discussion of the competencies and activities of the government agencies that regulate antitrust.

ANTITRUST REGULATION IN EUROPE AND INTERNATIONALLY

The foundation of antitrust regulation in the European Union is outlined in Articles 81 and 82 of the European Community Treaty. Article 81 outlawed agreements such as price-fixing and market sharing, and Article 82 made illegal the practice of predatory pricing aimed at eliminating competitors from the market. Although similar in spirit to antitrust policy in the United States, competition policy in the European Union is intended to advance economic integration among its members.

There has been increasing cooperation among countries in acting against international cartels. The efforts of law enforcement authorities are coordinated through the International Competition Network, an international body whose goal is convergence in the enforcement of antitrust regulation laws. In the first decade of the twenty-first century more than a hundred countries adopted antitrust laws.

LENIENCY PROGRAMS

Leniency programs are legal incentive schemes that offer the members of a cartel amnesty from prosecution if they report a conspiracy and cooperate with the investigation. The purposes of these programs include detection and successful prosecution of cartel members as well as destabilization of cartels and deterrence of their formation. The United States established a leniency program in 1993; the European Union adopted a revised leniency program in 2002. Countries such as Brazil, Canada, the Czech Republic, Germany, Ireland, Korea, Sweden, and the United Kingdom have used leniency programs as part of their antitrust enforcement efforts. Economists and game theorists increasingly are involved in the design of leniency schemes.

ANXIETY

Anxiety is a universally experienced emotion felt as an unpleasant, tense anticipation of an impending but vague threat. Some 18 percent of the adult U.S. population experiences anxiety symptoms to the extent that they can be diagnosed as suffering from an anxiety disorder. Anxious people often feel as if something bad were about to happen to them, although they might be unable to identify an immediate threat. The emotion of anxiety is in many ways similar to fear, although fear is typically defined as an emotional reaction to a clearly identifiable threat, such as a charging elephant or the possibility of falling when leaning over the edge of a tall building.

Fear and anxiety have in common several reaction patterns. One typical anxiety response is a sense of choking or constriction, felt as a lump in the throat. Indeed, the Latin root of the term *anxiety* is *angh*, meaning “constriction.” Also related is the Germanic word *angst*. However, an anxiety reaction is more than a lump in the throat, as described by psychologist Stanley J. Rachman, one of the leading authorities on anxiety and anxiety disorders. Most experts agree that there are three partially integrated response systems that account for the various symptoms and therefore make up the full experience of anxiety. These are the cognitive, physiological, and behavioral response systems. Examples of each are described in Table 1.

Sigmund Freud (1856–1939), the founder of psychoanalysis in the late nineteenth century, is credited with explication of the role of anxiety in afflicting people’s daily lives. Freud postulated three types of anxiety. He called a reaction to a real or potential threat reality anxiety, whereas anxiety generated within the psychic apparatus as a threat to the ego was called neurotic anxiety. According to Freud, the ego keeps its instinctual sources of threat out of conscious awareness so that the true source of neurotic anxiety remains obscure and is experienced as “free-floating” or unattached anxiety. Freud also described moral anxiety, arising from an impending or actual violation of internalized standards. Moral anxiety is experienced as shame or guilt.
Another, more recent characterization of anxiety types is psychologist Charles Spielberger’s state-trait distinction. State anxiety refers to an individual’s anxious feeling at a given time: “Are you anxious right now?” Trait anxiety refers to one’s state of anxiety in general: “Are you an anxious person?” State anxiety is more akin to fear as a response to a specific situation, whereas trait anxiety is part of one’s overall personality.

The most common source of anxiety or fear is the perception that one is in imminent psychological or physical danger, or might be at some future time, such as feeling anxious about an impending dental appointment. Another common source of anxiety is concern over what other people might think of you. This social anxiety is particularly prevalent among adolescents, who worry that they might be scrutinized by others and be found lacking in appearance, skills, or behavior.

Although most anxiety is precipitated by perceived environmental threats, there are clear individual differences in how people perceive and react to potential threats. There is good evidence that some people are genetically predisposed to be more anxiety-reactive than others. Furthermore, a number of physical and medical conditions can cause anxiety symptoms that resolve when the condition is successfully treated. A sample of these anxiety inducing medical conditions is shown in Table 2.

The experience of anxiety is virtually universal among humans and most vertebrate animals. Most anxiety is experienced within the normal range, where it escalates under perceived stressful situations (e.g., taking a test) and then diminishes as the threat wanes. However, for those whose anxiety is severe enough to be diagnosed as an anxiety disorder, the experience of anxiety is chronic, debilitating, and interferes with personal, social, and occupational functioning. The various disorders have in common an exaggerated sense of fear, anxiety, and dread; yet each has a distinctive pattern to its expression.

### Table 1

**Response components that make up the experience of anxiety**

| Cognitive: | Thoughts that something is wrong, a sense of dread, worry about many things, and difficulty concentrating. |
| Physiological: | Increased activation of the sympathetic nervous system leading to increases in heart rate, blood pressure, perspiration, respiration rate, pupil dilation, and muscle tension. |
| Behavioral: | Fidgeting, pacing, jittery movements, irritability, stuttering, flight from or active avoidance of a harmless but feared situation. |

### Table 2

| Physical conditions that can cause anxiety symptoms |
|------------------------------------------|------------------------------------------|
| **Disordered system** | **Example conditions or substances** |
| Endocrine disorders | hypoglycemia, hyperthyroidism |
| Cardiovascular disorders | mitral valve prolapse, angina pectoris, arrhythmia |
| Respiratory disorders | hyperventilation, chronic obstructive pulmonary syndrome |
| Metabolic disorders | vitamin B12 deficiency |
| Neurologic disorders | postconcussive syndrome, vestibular dysfunction |
| Toxins | paint, gasoline, insecticides |
| Drug intake | alcohol, amphetamines, sedatives, antihistamines |
| Drug withdrawal | sedatives, alcohol, cocaine |

Specific phobias are morbid and irrational (relative to the potential for actual danger) fear reactions to specific objects and situations. The phobic person attempts to avoid or escape from these objects or situations at all cost. Common examples include phobias of small animals (e.g., rats, snakes, spiders), heights, and injections of medicine. Social phobia involves fear and anxiety reactions to situations in which a person believes that he or she might be observed by others and be negatively evaluated or might embarrass himself or herself. Public speaking, using public restrooms, and eating in public are among the more common social phobia situations.

Generalized anxiety disorder involves a chronic state of worry, apprehension, and anticipation of possible disaster, no matter how unlikely it is that the disaster will occur. Individuals with panic disorder might have a sudden attack of intense anxiety or panic that hits them unexpectedly, out of the blue. In certain cases, when these unexpected panic attacks occur outside the home, people become fearful that another attack might strike if they go out again. When they become so fearful of having another attack that they cannot leave their home or safe haven, they are diagnosed as having panic disorder with agoraphobia. Posttraumatic stress disorder can occur following a terrifying event. The person might experience persistent, frightening thoughts and images as flashbacks to the original trauma. Individuals with obsessive-compulsive disorder experience anxiety-related thoughts and feel compelled to enact compulsive rituals, such as washing their hands repeatedly, lest they experience even more intense anxiety.

One of the most serious consequences of untreated chronic anxiety disorders, which are often accompanied by depression, is the increased risk of substance abuse as a form of self-medication. Other consequences of the con-
stant worry and accompanying physical tension are gastrointestinal distress, insomnia, headache, high blood pressure, hyperventilation, nausea, and fatigue.

Anxiety disorders are among the most successfully treated of all mental disorders. Two basic approaches contribute to this effectiveness: psychotherapy (specifically, cognitive-behavioral therapy) and pharmacotherapy. The effective therapeutic processes in cognitive-behavioral therapy include helping patients alter negative anticipatory thoughts that often trigger anxiety symptoms and helping them confront their feared situations directly, which allows the anxiety symptoms to dissipate. To facilitate these processes, training in cognitive coping skills and deep relaxation are typically included in a cognitive-behavioral therapy treatment protocol.

Two classes of drugs are known to be effective in treating some anxiety disorders. Antianxiety drugs, primarily benzodiazepines, can reduce anxiety and panic symptoms but they have the serious drawback of physical dependency if taken for extended periods. Many antidepressants, particularly selective serotonin reuptake inhibitors and tricyclics, also have antianxiety properties. Examples of these antianxiety drugs are listed in Table 3.

### APARTHEID

*Apartheid* is a word in Afrikaans that originally meant “apartness” or “separateness.” Now it is the internationally recognized term for the policies of strict racial segregation and political and economic domination of blacks (Africans, “Coloreds,” and Asians) pursued by the National Party government of South Africa from 1948 until its exit from power in the early 1990s.

Apartheid catapulted to prominence as a catchword used by the National Party in its successful 1948 electoral campaign to oust Prime Minister Jan Smuts and his United Party, who were accused of undermining racial segregation. The National Party, headed successively by Prime Ministers D. F. Malan, J. G. Strydom, H. F. Verwoerd, B. J. Vorster, P. W. Botha, and F. W. de Klerk, implemented an interlocking set of policies that together comprised apartheid: intensified segregation, “separate development,” and harsh political repression.

Intensified segregation was manifested in a plethora of new laws. Starting with the prohibition of marriage and sexual liaisons between races (Prohibition of Mixed Marriages Act, 1949, and Immorality Act, 1950), the National Party government defined criteria for racial categorization of individuals (Population Registration Act, 1950), mandated racially based residential segregation (Group Areas Act, 1950), required segregation of public facilities (Separate Amenities Act, 1953), established separate education for Africans (Bantu Education Act, 1953), banned trade unions from representing Africans in labor negotiations (Native Labour Act, 1953), and empowered government to reserve specific jobs for particular racial groups (Industrial Conciliation Amendment Act, 1956). State power confronted blacks at almost every turn.

“Separate development” distinguished post-1948 National Party policies from previous segregation in South Africa. All blacks were segregated residentially and commercially under the Group Areas Act. Millions of
blacks were forcibly removed from urban “white” areas into crowded “black” areas. Additionally Africans were assigned to ten ethnic “homelands” (based upon existing “tribal reserves”) that were to be the sole legitimate space for black political expression and representation under the Bantu Authorities Act (1951) and the Promotion of Bantu Self Government Act (1959). From 1976 onward four “homelands” (Transkei, Bophutatswana, Venda, and Ciskei) were granted fictive independence, recognized only by South Africa. “Coloreds” and Asians were granted nominal representation in separate political bodies.

Opposition to apartheid in the 1950s centered around the African National Congress (ANC), led by Nelson Mandela, Walter Sisulu, and Oliver Tambo. The ANC organized nonviolent campaigns of defiance and boycott in alliance with the South African Indian Congress, the South African Coloured People's Organization, and radical whites in the Congress of Democrats. In 1955 representatives of the congresses, led by the ANC, adopted the Freedom Charter, a document demanding full civil rights for all South Africans, an end to racial discrimination, and major economic reform, including selected nationalization. In 1959 the Pan Africanist Congress (PAC) broke from the ANC, accusing it of subservience to non-Africans and insufficient militancy. It echoed the ANC in calling for demonstrations against passes, the hated government control document carried by all Africans.

Following widespread demonstrations protesting the Sharpeville massacre of 1960—in which sixty-nine unarmed Africans were shot after responding to a PAC call to turn in passes and submit to arrest—the government embarked on sustained repression of opposition. Prior to 1960 it had generally respected legal norms, relying upon the Riotous Assemblies Act (1914) and its amendments (1927, 1929), under which the government could declare a state of emergency and ban individuals from political activity, and the Suppression of Communism Act (1950), which granted additional powers to block political activity deemed communist under a broad definition. In 1960 the government enacted the Unlawful Organizations Act, under which it banned the ANC and the PAC. It followed with General Laws Amendment Acts in 1962 and 1963 and the Terrorism Act of 1966, which legalized house arrest and detention without habeas corpus and provided greater penalties up to death for sabotage and terrorism. Concomitantly police adopted the practices of solitary confinement, physical and mental torture, and assassination.

In the view of the government, harsh police state measures were a necessary response to the decision of the ANC in 1961 to abandon nonviolence for armed struggle—to be led by Umkhonto we Sizwe (MK), a military organization jointly directed by leaders of the banned ANC and the clandestine South African Communist Party (SACP)—and to attacks on whites by POQO, an offshoot of the PAC, in 1962–1963. Relentlessly deploying its strengthened arsenal of repression, the government successfully decimated its internal opposition, as symbolized by the imprisonment in 1964 of ANC leaders, including Mandela and Sisulu, on Robben Island. Tambo, who had left the country in 1960, peripatetically undertook the difficult creation of ANC and MK structures in exile.

The Soweto uprising of June 1976 and the nationwide unrest that followed exploded the government’s hopes that blacks might acquiesce to apartheid. The government responded with both reform and repression. African trade union rights were recognized in 1980 and 1981, a new constitution was enacted in 1984 granting subordinate voting privileges to “Coloreds” and Asians, and there was selective relaxation of rigid segregation, including the abolition of the pass system in 1985. Repression of opposition was intensified, however, as symbolized by the 1977 death in police custody of Steve Biko, the charismatic leader who founded the Black Consciousness movement in the late 1960s. Nevertheless, opposition inside the country grew. Post-1976 boycotts, strikes, and township demonstrations metamorphosed in the 1980s into open nationally organized opposition, led by the ANC-oriented United Democratic Front (UDF), a burgeoning trade union movement, and prominent church leaders, most notably the 1983 Nobel Peace Prize winner Archbishop Desmond Tutu. Numerous acts of sabotage and armed attacks—organized by the resurgent ANC/MK underground and the ANC mission in exile—were carried out, complementing the external opposition of the worldwide antiapartheid movement and increasingly extensive economic sanctions.

On February 11, 1990, the newly elected president deKlerk freed Mandela and other ANC leaders from prison and legalized the PAC, ANC, and SACP. Negotiations between the National Party, headed by deKlerk, and its erstwhile antiapartheid opponents led by the ANC, headed by Mandela, commenced in mid-1990, leading in late 1993 to agreement upon a new nonracial democratic constitution. In 1993 the last apartheid laws were repealed.

In South Africa’s first election under the new constitution in April 1994, the ANC won a majority of votes, and Mandela became president. Mandela vigorously pursued a policy of reconciliation with those who had supported apartheid. The Truth and Reconciliation Commission, headed by Archbishop Tutu, exposed the workings of the apartheid police state. The ANC-led government adopted policies to reverse the consequences
of decades-long apartheid, but apartheid’s entrenched legacies of inequality and black poverty proved hard to overcome.

APPALACHIA

The Appalachian Mountains range southwestward from Quebec and Newfoundland in Canada to Alabama in the southeastern United States. The central and southern highlands of this ancient mountain range, consisting of the Blue Ridge and Smoky Mountain ranges, the Allegheny and Cumberland plateaux, and the Great Valley in between, are frequently thought of as comprising a distinct sociocultural region known as “Appalachia.”

The Appalachian Regional Commission (ARC) defines Appalachia as 406 counties found in 13 states, including all of West Virginia plus portions of Alabama, Georgia, Kentucky, Maryland, Mississippi, New York, North Carolina, Ohio, Pennsylvania, South Carolina, Tennessee, and Virginia. A more common geographical definition of Appalachia includes the ARC-designated counties in West Virginia, Kentucky, Ohio, Maryland, Tennessee, North Carolina, Virginia, and Georgia.

EARLY POPULATION

A diverse population of Native Americans has lived in the mountain South for around three thousand years. The Iroquois, who were the dominant group in the region, came from the west around 1300 BCE and split into the northern Iroquois and the southern Cherokees. The Cherokees were farmers and hunters who lived in small independent villages.

Although Indians in the Appalachians had sporadic contacts with Europeans as early as 1540, it was not until the period 1700 to 1761 that contact between the two cultures accelerated. The Europeans looked to the backcountry for room to expand their settlements and for sources of skins for trading. The Indians opposed them in an ultimately futile attempt to save their homes and hunting grounds. The final defeat of the Cherokees by the British occurred in 1761, and after this date the number of whites in the Appalachian frontier grew rapidly. The conquest of the Indian lands encouraged settlement, and land speculation in the Appalachian frontier ran rampant.

The areas from which the earliest European settlers in Appalachia came and the routes they took into the backcountry helped form Appalachian culture. There were three major reservoirs of population from which people flowed into the Appalachian region in the eighteenth century: the central valley of Pennsylvania, the Piedmont of North Carolina, and western Pennsylvania. The earliest European immigrants into the Appalachian frontier came from eastern Pennsylvania. Around 1720 the German and Scotch-Irish populations around Philadelphia began to move first into central Pennsylvania, then southward into the Shenandoah Valley. Over time they and their descendants pushed south toward the New River, but instead of crossing the mountains into Indian country, they turned southeastward toward the Carolina Piedmont.

By the middle of the eighteenth century this area became a second population reservoir that fed migrants into the mountains. It was the source of early settlers into far southwestern Virginia, western North Carolina, and upper eastern Tennessee. By 1760 a significant number of Germans and Ulster Scots were also coming into Appalachia from western Pennsylvania. These people drifted down the Ohio River, then followed tributaries into the mountains.

By 1763, in clear violation of the English Proclamation of 1763, settlers began to migrate into the western reaches of North Carolina, the river valleys of the Tennessee-Virginia border country, and, just a few years later, even into central Kentucky. The most important of the communities they formed were the Watauga settlements in eastern Tennessee, the Holston settlements of far southwestern Virginia and western North Carolina, and the Boonesborough and Harrodsburg settlements laid out by Daniel Boone after he traversed the Cumberland Gap in 1775. Although many of these people did not own the land they lived on, and acted as agents for absentee owners, it is nonetheless significant that on the eve of the American Revolution there were scattered settlements deep in the American frontier. The population of the
southern mountains grew steadily from the 1760s until the 1820s.

CIVIL WAR ERA AND INDUSTRIALIZATION
The society that emerged in the mountains was not unlike other rural American farm regions that were not far removed from their frontier origins, and that were dominated by connections between land, family, and work. Until the era of industrialization Appalachia was a region of small, open-country communities, concentrated in valleys and up into mountain coves and hollows. The separate settlements were integrated by transportation and communication systems, but only loosely. Each community of farmsteads was relatively self-sufficient socially and economically, and people tended to avoid routinely crossing mountains to reach another community, if possible.

What held these scattered farms together and molded them into some semblance of community was a shared sense of identity, common values, and shared work. People exchanged food and shelter, worshipped in small, independent congregations, engaged in cooperative community service, had a sense of belonging to a larger group of friends and neighbors, and were united in their love of the land and the place they lived.

The mountain economy was also similar in many ways to other preindustrial economies in rural America. There was a preponderance of noncommercial, semi–self-sufficient farms, although in some areas of Appalachia farming for an external market was common. Some industries also emerged in the mountains before the Civil War, but were not significant regionally and had only a marginal effect on the total economy.

Although the issue of slavery did not emerge in Appalachia as the dominant controversy of the Civil War era, the war did have an impact in the mountain areas of the South. The relative absence of slavery in the mountains was the result of the geographic and economic conditions found there. Because of the mountain terrain, it was simply not profitable to develop commercial agriculture based upon a slave workforce, and what slavery did exist in Appalachia was concentrated in the larger valleys of Virginia and Tennessee. There was considerable industrial slavery in Appalachia in the tanning works, salt mines, and iron foundries of Virginia, and in the brick mills of Tennessee and Kentucky.

As the result of their Civil War experiences, a great many northerners came into contact with the southern mountains, and many were surprised by what they found. Great mineral and timber wealth was coupled with a romantic beauty, just at a time when untamed urban growth, foreign immigration, and technological developments were beginning to unalterably change northern urban society. Capitalists responded to the call of profits, but writers, missionary workers, and teachers accompanied the industrialists into the mountains, and their work there was in some ways as substantial and the effects as long lasting as those of their entrepreneurial counterparts.

The dominant stereotype of Appalachia that was formed during this era of industrial development was ironically an image of a society that still held within it much of its late-eighteenth-century frontier heritage. Mountain people were described as noble and savage, independent, proud, rugged, and violent, but also as dirty and uneducated, yet crafty and practical. They drank too much and were lazy, but managed to produce excessively large families.

The people who were mostly responsible for this image of Appalachia were a group of writers in the Local Color Movement. They described in influential journals, short stories, novels, and travel literature a land of contemporary ancestors who were more Elizabethan than American. Violence, feuding, moonshining, and a traditional culture existed in an Appalachia that had been untouched by the forces of modernization. Appalachia began to be thought of as a region in stark contrast to the progressive, urban culture of the rest of the United States.

One of the results of this new image of Appalachia was the urge felt mostly by middle-class women who came into Appalachia from the Northeast to improve conditions in the mountains and uplift Appalachian culture. They typically perceived the regional culture as deficient in many ways, and they worked diligently to bring schools and modern middle-class values to mountain people.

A second feature of the response to this new image of Appalachia was cultural preservation. What certain cultural workers thought represented the best of mountain culture was preserved and protected from contamination by the evils of modernization. This work to preserve mountain ballads, folk crafts, and dances was carried out by traveling folklorists such as Cecil Sharp and at folk schools such as the one founded by John C. Campbell. What they chose to preserve and value did not always reflect the reality and variety of Appalachian culture, but rather the image that was created and perpetuated by the cultural workers themselves.

A third response to the backward image of Appalachia was to use economic development and industrialization to promote progress, because the local population was believed to be incapable of developing Appalachian resources on its own. Promoters of this idea asserted that economic development would provide needed discipline and order in the mountains, and that through industrialization the Appalachian people could become effective contributors to the progress of the nation. Both technological innovations and rapid urban
growth created demands for labor, minerals, and timber, all of which were in abundant supply in Appalachia. Industrialization depended first upon the building of an adequate transportation system into, out of, and within the mountain regions of the South.

The great era of railroad building in Appalachia lasted from 1870 to 1910. By the end of this period the rail network reached into nearly every county by either a main or branch line. The impact of the railroads on every facet of life in Appalachia is hard to overestimate, but the most immediate effect was to open the doors to full exploitation of the region's natural resources.

Coal was the primary resource that drove the Industrial Revolution in Appalachia. The ambitious men who opened and operated the mines were outsiders from middle- or upper-middle-class backgrounds who established the company town system in Appalachia and wielded enormous political and economic power in the coal fields and beyond. They manipulated the local and state political system to their industry's benefit, sometimes to the long-term detriment of the local economy. The laborers who worked in the mines and moved their families into company towns to live were a varied lot. They were primarily native Appalachians, southern blacks, and immigrants from southern and eastern Europe.

Although coal mining was certainly the most important industrial development in Appalachia, it was not the only one. From 1880 to 1930 industrialization also showed up in forestry and timber exploitation, textile mills, railroading, non-coal mineral mining, and chemicals production.

The impact of industrialization in Appalachia was tinged with good and bad features. At the end of this era, fully two-thirds of Appalachian people made their living from nonfarm work. The economy had moved, by World War I, from a local or regional orientation to a national and international one. Although most mountain people no longer gained their primary incomes from the land, an attachment to the land remained an important regional value. People still farmed on a part-time basis, growing large gardens and raising some livestock. Older values such as strong family ties and conservative religious beliefs remained central to regional culture despite the wrenching economic and social changes of the late nineteenth and early twentieth centuries.

One of the most important results of industrialization in Appalachia has been the negative impact it has had on the long-term economic health of the region. None of the industries in Appalachia, and especially not the coal industry, encouraged rival or spin-off economic development during their boom years. The effect has been sporadic economic growth without real economic development.

POSTWAR TO THE PRESENT
World War II and the years immediately following it were turning points in the history of Appalachia, just as they were for the rest of the United States. Once they returned home from their wartime experiences, many young men and women focused on the lack of economic opportunities in Appalachia, and began to move out of the region in search of better jobs. This resulted in a great out-migration from Appalachia to the North and Midwest. Between 1945 and 1965 nearly 3.5 million people left Appalachia in search of a brighter economic future in major cities in the Midwest. Sizeable subcultures of Appalachian migrants built up in these cities.

Despite the general prosperity in the United States, the 1950s was a time of extreme poverty in Appalachia. A renewed national attention to Appalachia was accelerated by the campaign for the Democratic presidential nomination in 1960 when the major candidates visited West Virginia. After he became president in 1963, Lyndon Johnson pushed the Appalachian Regional Development Act through Congress. The bill called for federal funding for secondary and vocational education programs, highway construction, timber management programs, and widespread promotion of tourism.

Most historians think that though the War on Poverty had some successes, it generally failed in Appalachia. The heritage of the billions of dollars spent on highways and industries in the mountains has been continued poverty amidst pockets of prosperity. Economic development in the 1970s consisted of the coal boom of 1974 to 1978, the tourism-generated land boom in eastern Tennessee and western North Carolina, a growth in textile production, some small-scale component-part manufacturing, and the growth of large-scale chain stores and fast-food establishments located within the more prosperous areas. Outside the few growing towns and cities, there are rural areas where poverty is still the norm.

One important result of the War on Poverty in Appalachia was the emergence by the late 1970s of a strong sense of regional identity and the need to express a positive image of Appalachia when writing or talking about its people, history, and culture. Even the word Appalachia became more accepted than it had ever been. To many within the region, the culmination of the organizing and turbulence of the 1960s was an Appalachian Renaissance filled with a strong dose of regional pride that was associated for this first time in American history with being from the mountains.

Appeasement

Appeasement is a foreign policy strategy of making concessions to an adversary in order to avoid direct military conflict. As a foreign policy strategy it is rarely advocated today, largely as a result of the failure of British diplomacy vis-à-vis Nazi Germany in the later 1930s. It remains a central concept beyond this historical moment, however, in that it is often invoked in foreign policy debates in the United States and elsewhere as a term of opprobrium to describe concessions to adversaries. Appeasement is not necessarily a policy resulting from fear and weakness, however; it has the potential to be effective if political leaders can understand the distribution of power in the international system.

THE IDEA OF APPEASEMENT

According to the Oxford English Dictionary (1993), the term appease means, “to bring peace” and was first used in English around the thirteenth century. Appeasement, thus, means “pacification” or “satisfaction.” Because it implies the satisfaction of the demands rather than the requests of an aggrieved party, appeasement has had an underlying negative connotation even when used to describe interpersonal relations. But its strongly negative connotations did not solidify in the English-speaking world until after World War II (1939–1945). Various dictionaries and encyclopedias of the social and political sciences demonstrate this negative valence quite clearly. One author, for example, describes the policy as the “surrender of a vital interest for a minor quid pro quo, or for no reciprocal concession at all” (Plano and Olten 1982, p. 229).

Despite this generally negative valence, however, some have described the policy in more positive ways: for example, as a form of conflict resolution (Walker 2005). Indeed, satisfying the demands of an opponent in order to avoid war need not be a negative policy, especially if the opponent is viewed as having been unfairly treated in the past. Conflict resolution often requires the granting of concessions, something that, while very few would call it appeasement, is not that far from the policies that were identified as such in the late nineteenth and early twentieth centuries.

BRITISH INTERWAR DIPLOMACY

Appeasement as a foreign policy strategy is most closely associated with British policies in the interwar years (1919–1939). Martin Gilbert in his The Roots of Appeasement (1966) gives the clearest analysis of British appeasement policies. He argues that they should be seen as resulting from a combination of guilt over the harshness of the Versailles treaty, liberal policies favoring economic interdependence, and an abhorrence of war. The end of the “Great War” led to the Paris Peace Conference, during which the allied powers sought to both impose a settlement on Germany and create new institutions that would, it was hoped, eliminate war in the future. Although a desire for revenge animated many at the conference, others sought to counter those impulses. During the conference David Lloyd George, the British prime minister, authored the famous Fontainebleau Memorandum, which sought to limit the harshness of the reparations scheme, a proposal that Gilbert sees as being in the spirit of appeasement.

Appeasement during the interwar period revolved around two issues: reparations and rearmament. After the Versailles settlement, British policymakers soon recognized the precarious position in which Germany had been placed by the imposition of harsh reparations. John Maynard Keynes’s influential book The Economic Consequences of the Peace (1919) supplied the foreign policy community with strong economic reasons for decreasing reparations. In 1924 the Dawes Plan—the result of an American-led commission, but largely inspired by British attempts to improve the German economic situation—resulted in a reduction of German war reparations. The Young Plan of 1929 further reduced the burden of reparations, which were eventually abolished at the Lausanne Conference in 1932 (Carr 1947).

While the decrease in German reparations payments was generally perceived as positive, concessions on security agreements were more controversial. The Versailles settlement included the provision that the Rhineland was to be occupied for fifteen years by Allied forces and per-
manently demilitarized. Stringent limits were also placed on German armed forces. These limits were violated soon after Adolf Hitler came to power in 1933. Quickly dismantling any semblance of constitutional government in Germany, Hitler began the process of rearming the German nation. On March 7, 1936, Germany remilitarized the Rhineland, a move some British leaders considered acceptable, as in their view it rectified the unjust division of Europe created by Versailles (Rock 1977, p. 38). Others in the British political system, however—most prominently, Winston Churchill and Anthony Eden—were beginning to see the folly of appeasing the Nazis.

At this point, the policy of appeasement began to appear as one of weakness rather than strength. In March 1938, the Germans annexed Austria, an action that resulted in the British undertaking a high-level policy review of relations with Germany. Rather than seeing this as an opportunity to halt an aggressive dictator, however, British leaders proposed to further appease Hitler in order to avoid another shock to the fragile European system. When German troops began massing near the Sudetenland, a region of Czechoslovakia with a large percentage of German speakers, the British sought to convince Prague of the wisdom of appeasement. Failing to convince the Czechs to accept German demands, the British sought to negotiate directly with Germany. After two separate trips to Germany to convince Hitler to moderate his demands, in late September 1938 Prime Minister Neville Chamberlain flew to Munich, where an agreement was signed (without a Czechoslovakian signature) giving the Germans the Sudetenland. Germany occupied the rest of Czechoslovakia in March 1939, leading the British to finally stand up to Hitler by guaranteeing the borders of Poland. When Hitler attacked in September 1939, war erupted and appeasement lay in ruins.

**APPEASEMENT SINCE WORLD WAR II**

In the postwar period, *appeasement* quickly became a term used to identify a failed or misguided policy. British and American policymakers, emboldened in the cold war, refused to “appease” the Soviet Union when faced with its aggressive policies. In 1956 Prime Minister Anthony Eden, who had resigned from the British government in the 1930s over appeasement policies, intervened in Egypt with the French and Israelis because he believed that concessions to Nasser would be a new form of appeasement. American president Lyndon Johnson’s unwillingness to back out of the Vietnam War resulted, in part, from his refusal to appease Ho Chi Minh. In the United States’ long war with Iraq, both Democratic and Republican leaders (for example, the Democratic secretary of state Madeleine Albright and the Republican vice president Richard Cheney) claimed that to give into Saddam Hussein would be Chamberlain-esque appeasement all over again.

This reflexive view of appeasement as weakness, however, misunderstands its potential. Paul Kennedy points out that appeasement arose from a British tradition of ethical foreign policy reaching back to nineteenth century, when William Gladstone sought to create a foreign policy grounded in peace and economic prosperity. Great powers can indulge in policies of appeasement in order to manage the international system, as Kennedy argues the British did in their relations with the United States during the latter half of the nineteenth century when they allowed an emerging power to take control of the Western Hemisphere (Kennedy 1976).

If an adversary seeks a change in the international system that does not weaken but might actually improve the position of the stronger power, a policy of appeasement might well be a wise move. It is only when it is undertaken in response to the demands of a powerful state bent on aggrandizement that appeasement can be deemed a policy failure. This suggests that appeasement can only succeed if leaders can correctly appraise the distribution of power in the international system. When an adversary who is weak makes demands that will not necessarily increase its strength too much, appeasing those demands might decrease conflict in the future. At the same time, by constantly conceding to demands from different powers, a great power might eventually undermine its ability to deter others in the system.

The realist policy of maintaining a balance of power might include appeasement at key moments, in order to ensure stability. E. H. Carr, one of the leading realists of the twentieth century, suggested in his classic *Twenty Years Crisis* (1940) that British appeasement was a realist policy, in that it combined the interests of Britain with an honest appraisal of power—although in later editions, Carr excised those passages in which he justified appeasement (Hall 2006).

The normative foundations of appeasement that underlay British policies toward Germany in the interwar years correspond with the goals of modern liberal internationalism: defusing conflict, rectifying unjust settlements, and avoiding war. British policymakers’ inability to appreciate the emerging power of Germany prevented them from seeing how their good intentions could lead to war. The disastrous consequences of their policy choices continue to influence how appeasement is understood today. Although it is difficult to change the word’s connotations, appeasement, from a position of strength, should also be seen as a means to avoid conflict.

APPORTIONMENT
The term appportionment refers to the decennial process that divides membership in the U.S. House of Representatives among the fifty states according to the size of the states' populations. After appportionment, state governments initiate redistricting, the highly contentious process of revising the intrastate boundaries of the House districts. Article I, Section 2 of the U.S. Constitution mandates that appportionment take place every ten years, and Congress is given the responsibility of managing the procedure. Two amendments to the Constitution influence appportionment: Amendment 14, Section 2 repealed the original provision that considered nonfree persons (slaves) as three-fifths of a person for counting purposes, and Amendment 16 released the federal government from the original bind of having to use a state’s population as a basis for determining tax levies.

The Constitution entitles each state to have at least one representative in the House, with the “respective numbers” of each of the states forming the basis for the further distribution of seats. Congress has the power to define the precise manner of dividing up House seats, and this process has been a continuous source of controversy. In issuing his first presidential veto, George Washington “rejected a formula designed by New York's Alexander Hamilton for allocating seats after the 1790 census” (Prewitt 2000, p. 2). More recently, a 1998 U.S. General Accounting Office paper noted that after the number of available House seats was fixed at 435 in 1911, “a gain of representation for any one state came only with a loss of representation for another state” (p. 10). Orville J. Sweeting notes that the cap was instituted because “the House threatened to become so large, if size continued to follow population growth, that it could not properly transact its business” (1956, p. 440).

Southern and rural members of Congress were so fearful of the consequences of losing their seats due to the urban and northward shift of the population that they prevented the constitutional mandate of apportionment from taking place during the 1920s. Although apportionment has occurred in every decade since the 1930 census, the political battles associated with the process have not subsided. As currently written, Title 2 of the U.S. Code requires the use of the “method of equal proportions” to determine the allotment of seats among the states, as described in an online document produced by the Census Bureau. This method has been in place since the apportionment associated with the 1940 census, and it was upheld as constitutional by the Supreme Court in 1992 in the case of United States Department of Commerce v. Montana.

In the prelude to the 2000 census, there was a strong debate over whether statistical sampling to adjust for census undercounting could be used in the apportionment process. In 1999, the Supreme Court’s five-to-four ruling in Department of Commerce v. United States House of Representatives affirmed that Section 195 of Title 13 of the U.S. Code prohibits the use of statistical sampling, but the Court explicitly declined to rule on the constitutionality of using sampling should this section of the code be repealed.

**APPROPRIATIONS**

Appropriations are legislative acts that authorize the withdrawal of public money from the treasury to fund government programs. Thus, appropriations measures provide the legal authority to spend government money, but are distinct from the act of spending. For example, the legislature could appropriate $100,000 for a public-works program, but the agency responsible for the work could spend only $50,000 to complete the program.

Generally, the two main types of appropriations measures in the United States are for mandatory spending and for discretionary spending. Appropriations for mandatory spending are budget authority for entitlement programs, such as Social Security, set by legal parameters (confusingly, this budget authority is generally considered outside the appropriations process). Appropriations for discretionary spending are budget authority for annual measures. The main work of the Appropriations Committees of the House of Representatives and the Senate is to hold hearings concerning appropriations measures for different areas of discretionary spending. In 2007, there were thirteen areas of discretionary spending: agriculture; commerce, justice, and state; defense; District of Columbia; energy and water development; foreign operations; homeland security; interior; labor, health and human services, and education; the legislative branch; military construction; transportation; veterans administration; and housing and urban development.

The appropriations process is distinguished from many other forms of legislation considered by Congress because of the legally proscribed budgetary cycle. The annual appropriations cycle begins near the start of each calendar year when the president submits his annual budget for the upcoming fiscal year with recommended spending levels. Congress is required by law to respond to the president by passing an annual budget resolution. This resolution provides a guide for subsequent congressional action by setting spending ceilings for the different areas of discretionary spending and by projecting appropriation levels for the next five fiscal years. Once the budget resolution is passed, the legislation is referred to the Appropriations Committees of the House and Senate, and the legislative process continues in much the typical manner.

From the mid-1990s Congress has had increasing difficulty passing separate appropriations bills for the different areas of discretionary spending. This can create problems for government operation because if Congress fails to pass appropriations legislation in time for the next fiscal year, the effected programs lose the authority to spend and must shut down. To prevent the shutdown of government operations, Congress may pass a continuing resolution to provide temporary funding. To speed the legislative process, appropriations measures have been passed with increasing frequency as omnibus legislation that packages multiple areas of spending into one bill.

Article 1, section 9, of the Constitution states, “No Money shall be drawn from the Treasury, but in Consequence of Appropriations made by Law; and a regular Statement and Account of the Receipts and Expenditures of all public Money shall be published from time to time.” Because the passage of legislation requires the approval of the legislature, this provision provides a strong constitutional check on the president’s ability to act without the approval of Congress. Article 1, section 8, of the Constitution gives this check additional weight in military matters by prohibiting congressional appropriations to raise and support armies for more than two years, thereby restricting the legislature’s ability to cede full control over the army to the president, who already serves as commander in chief of the military.

**ARAB LEAGUE, THE**

Officially known as the League of Arab States and consisting in 2006 of twenty-two countries, the Arab League was formed in 1945 by the governments of the then-independent or semi-independent Arab counties of Egypt,
Syria, Lebanon, Transjordan (now Jordan), Iraq, Saudi Arabia, and Yemen. Other Arab countries joined the League as they became independent, including Algeria, Bahrain, Comoros, Djibouti, Kuwait, Libya, Mauritania, Morocco, Oman, Qatar, Somalia, Sudan, Tunisia, and the United Arab Emirates. In addition, the Palestine Liberation Organization (PLO), while not ruling a sovereign territory, was granted full membership in 1976 as the representative of the Palestinians. In 2003 Eritrea became an observer, but has not pursued full membership.

The main purpose of the Arab League is to provide a forum for coordinating policies concerning education, finance, law, trade, and foreign policy among signatory members, and to help resolve their disputes. The secondary institutions that have resulted from that mandate coordinate developments in such areas as communication, transport, construction, medicine, and some minor industries. The Arab Common Market, established in 1965, has generally failed to live up to its expectations and original goals of abolishing custom duties, free movement of capital and labor among member countries, and coordination of economic development.

The most visible feature of the Arab League, however, is its political role as a governmental forum for common Arab national concerns, showcased in its highly publicized, though usually ineffectual, summit meetings. Historically the League sustained a consensus on supporting the independence of still colonized Arab countries. In the same spirit it opposed the creation of the state of Israel in 1948, and for decades supervised a joint Arab boycott of Israel and of companies doing business with it. For ten years after 1979 the League suspended Egypt’s membership because of its treaty with Israel—a treaty that violated a prior principle of coordinating Arab policies regarding the Jewish state—and moved its headquarters from Cairo to Tunis, where it remained until 1991 before returning to Cairo.

The political history of the Arab League has often been characterized by factional infighting among member states, which during the cold war took the form of a split between pro-Soviet and pro–United States regimes. A unified stance vis-à-vis Israel was broken when Egypt, Jordan, and the PLO signed separate agreements with Israel, although a semblance of a common position reemerged once the peace process stalled. With the notable exception of Syria, the League also held a unified position supporting Iraq during the devastating Iran-Iraq War (1980–1988). However, it was thrown into turmoil after the Iraqi invasion of Kuwait in 1990, which highlighted a low point in inter-Arab rivalries and also violated the League’s charter prohibiting the use of force by member states against each other.

Generally the Arab League is regarded not to have been successful in effectively promoting Arab unity and even coordinating policies, and many Arab governments are reluctant to agree to reforming and strengthening the League so that it could better pursue its aims. However, as a highly publicized forum for Arab governmental discussions, the League maintains an important symbolic status as a voice of a common aspiration for more Arab unity and coordination.

**ARAB-ISRAELI WAR OF 1967**

The Arab-Israeli War of 1967, also known as the Six-Day War, erupted between Israel and several of its neighbors on June 5, 1967, lasting until June 10. When the war was over, Israel had soundly defeated the militaries of Egypt, Syria, and Jordan and seized large amounts of territory, including the Old City of Jerusalem and its attendant holy sites, the Sinai Peninsula, the Gaza Strip, the West Bank, and the Golan Heights. The war transformed the political landscape of the Middle East from a military contest between Israel and its neighbors into (the 1973 Arab-Israeli War notwithstanding) what was primarily a political struggle between Israel and the more than a million Palestinians under Israeli occupation.

**THE POLITICAL BACKGROUND**

The Six-Day War had its roots in the creation of the Palestine Liberation Organization (PLO) by the Arab League in 1964. While Arab national armies had already been defeated twice by Israel (in 1948 and 1956), the creation of the PLO allowed Palestinian nationals to attack Israel directly and without support from the weakened Arab states in their quest to destroy the Jewish state and create a Palestinian homeland. In 1965 the PLO began attacking Israel from bases in Egypt and Jordan. Despite the fears of Egypt and Jordan that the aggression might lead to a general war, the PLO attacks increased in num-
ber and scale, from 35 in 1965 to 41 in 1966 and 37 in the first four months of 1967.

Furthermore, tensions had been steadily rising between Israel and Syria over Israel’s National Water Carrier irrigation project, which channeled water through the Jordan River for use in Israel. A Syrian project begun in 1964 attempted to divert the flow of water; Israel responded in 1965 by bombing the Syrian diversionary project. In retaliation, Syria bombarded Israeli villages and farms in the northern part of the country. A particularly deadly attack on April 7, 1967, provoked Israeli retaliation and six Syrian MiG fighters were shot down.

The Soviet Union, a major patron and ally of both Egypt and Syria, issued warnings on May 13 (now known to be false) that Israel was preparing for an invasion of Syria, prompting Syria to invoke its mutual defense pact with Egypt. The reasons for the Soviet deception are still unclear. Some believe that the Soviets hoped the increasing U.S. involvement in Vietnam would prevent their assisting Israel, creating an opportunity to seriously damage Israel and bolster Egyptian president Gamal Abdel Nasser’s power and prestige. It is also possible that the Soviets hoped Israel would prevail and remove Nasser from the scene, to be replaced by a more stable and predictable leader. Either way, despite assurances from UN observers that there were no signs of Israeli troop buildups or preparations for invasion on the Israeli-Syrian border, both Syria and Egypt accepted the Soviet warnings and initiated plans for an invasion of Israel.

THE WAR

On May 15, 1967, Egypt began moving troops into the Sinai Peninsula and massing them near the Israeli border. This was followed on May 18 by a Syrian mobilization that moved forces into position along the Golan Heights. On the same day President Nasser demanded that the United Nations Emergency Force, which had been stationed in the Sinai as a buffer between Israel and Egypt since the 1956 war, be withdrawn. United Nations Secretary-General U’Thant complied with the demand, in spite of a prior promise to take any such request before the UN General Assembly.

The withdrawal of the UN troops was quickly followed by an Egyptian blockade of the Strait of Tiran, Israel’s only supply route to Asia and the main shipping lane for oil from Israel’s largest supplier. Israel had made it clear that any attempt to close the strait would be considered cause for war and, following the 1956 Suez Crisis, had been given assurances by the United States and the United Nations that Israel had right of access to the Strait of Tiran. However, when Israel asked the major world powers to enforce those assurances, Great Britain and France reneged. The United States offered to form an international armada to break the Egyptian blockade, a proposal Israel accepted, although it was expected to take several weeks to assemble the armada and despite the worsening situation in the Sinai and Golan Heights.

On May 30, responding to pressure for Arab unity, Jordan joined the military alliance between Egypt and Syria. This, along with the entrance of Iraq into the alliance on June 4, brought the combined size of the Arab armies to approximately 465,000 troops, 2,880 tanks, and 810 aircraft. Against that force the Israel Defense Forces (IDF) mustered 275,000 troops (including reservists), 1,100 tanks, and 200 planes. Israel’s demographics (a relatively small population of around 2.3 million in 1967) and military structure (a small standing army backed by large numbers of reservists who could be called into duty when needed) made it difficult for the army to stay mobilized for long periods of time without doing massive damage to the domestic economy. Faced with hostile armies seemingly gearing up for war on all sides, the closure of a major shipping route, and the prospect of a troop mobilization with no immediate end in sight, Israel chose to launch a preemptive strike.

Prelude to War

On May 15, 1967, Egypt began moving troops into the Sinai Peninsula and massing them near the Israeli border. This was followed on May 18 by a Syrian mobilization that moved forces into position along the Golan Heights. On the same day President Nasser demanded that the United Nations Emergency Force, which had been stationed in the Sinai as a buffer between Israel and Egypt since the 1956 war, be withdrawn. United Nations Secretary-General U’Thant complied with the demand, in spite of a prior promise to take any such request before the UN General Assembly.

The withdrawal of the UN troops was quickly followed by an Egyptian blockade of the Strait of Tiran, Israel’s only supply route to Asia and the main shipping lane for oil from Israel's largest supplier. Israel had made it clear that any attempt to close the strait would be considered cause for war and, following the 1956 Suez Crisis, had been given assurances by the United States and the United Nations that Israel had right of access to the Strait of Tiran. However, when Israel asked the major world powers to enforce those assurances, Great Britain and France reneged. The United States offered to form an international armada to break the Egyptian blockade, a proposal Israel accepted, although it was expected to take several weeks to assemble the armada and despite the worsening situation in the Sinai and Golan Heights.

On May 30, responding to pressure for Arab unity, Jordan joined the military alliance between Egypt and Syria. This, along with the entrance of Iraq into the alliance on June 4, brought the combined size of the Arab armies to approximately 465,000 troops, 2,880 tanks, and 810 aircraft. Against that force the Israel Defense Forces (IDF) mustered 275,000 troops (including reservists), 1,100 tanks, and 200 planes. Israel's demographics (a relatively small population of around 2.3 million in 1967) and military structure (a small standing army backed by large numbers of reservists who could be called into duty when needed) made it difficult for the army to stay mobilized for long periods of time without doing massive damage to the domestic economy. Faced with hostile armies seemingly gearing up for war on all sides, the closure of a major shipping route, and the prospect of a troop mobilization with no immediate end in sight, Israel chose to launch a preemptive strike.
On June 9, the UN Security Council enacted a cease-fire that left Israel in control of the Sinai; Israel accepted the cease-fire immediately, and Egypt followed suit on June 10.

While Israeli tanks were driving through the Sinai, Israel was trying to keep the other major fronts in Jordan and Syria quiet, in accordance with the preferred Israeli strategy of fighting on only one front while holding the others. Israel had warned Jordan's King Hussein to stay out of the conflict, claiming that Israel had no intention of attacking Jordan, Jerusalem, or the West Bank. Israel also indicated its willingness to absorb a so-called barrage of honor, whereby Jordan could shell certain Israeli positions to fulfill its alliance commitments without provoking an Israeli response. However, when the Jordanian artillery barrage expanded and the Jordanian army moved to occupy a UN observation post in Jerusalem, Israel seized the opportunity to reunify Jerusalem and eliminate the Jordanian presence on the west bank of the Jordan River.

Israeli soldiers and paratroopers began moving toward the Old City of Jerusalem on June 5 and by June 6 had encircled the walled city. Israeli tanks also began sweeping through the West Bank, seizing the towns of Ramallah, Latrun, Jenin, and Nablus, in the process opening the Tel Aviv–Jerusalem road for the first time since 1947. Early on the morning of June 7, Israeli paratroopers broke through Jordanian resistance, entered the Old City of Jerusalem, and seized the Temple Mount, home of holy sites for both Jews (the Western Wall, the last remaining structure from the Second Temple of King Solomon) and Muslims (the Dome of the Rock and al-Aqsa mosques), reuniting the divided city of Jerusalem. Later the same day, Israeli forces occupied Bethlehem and Hebron, placing the entire West Bank under Israeli control. Fighting between Israel and Jordan ended on June 7 as both sides accepted a UN Security Council call for a cease-fire.

On the northern front, Israel and Syria limited their exchange to artillery barrages for the first four days of the war. Israel was content to postpone an invasion of Syria until after Egypt and Jordan had been dealt with, while Syria, despite all the prewar bluster and alliances, seemed satisfied to hang back and leave Egypt to the Israelis. However, Israel began to fear that a cease-fire might take effect before Israel had the opportunity to seize the Golan Heights. On June 9 Israel began an offensive to push the Syrians away from the Syrian-Israeli border and Israel's northern villages and farms. Israeli armored units quickly punched holes in the Syrian defenses and pushed deep into the Golan. By the end of June 10, Israel had occupied the entire Golan Heights. The acquisition of the Golan Heights, along with the Gaza Strip, West Bank, and Sinai Peninsula, more than tripled Israel's previous size. The new territory gained the country important strategic positions, but also created a perennial political problem: Israel now occupied territories inhabited by more than a million Palestinians.

Over the course of the Six-Day War, Israel defeated the combined armies of three Arab nations at a relatively low cost to its own troops. All told, Israel lost approximately 800 soldiers, with about 2,500 wounded and 18 taken prisoner or missing. Egyptian losses were the heaviest: between 10,000 and 15,000 dead, 15,000 wounded, and 5,500 taken prisoner. Jordan had about 2,000 soldiers killed and 5,000 wounded, while Syria had 700 dead, 3,500 wounded, and 500 taken prisoner.

THE POLITICAL AFTERMATH
The Six-Day War is, unquestionably, one of the seminal events in the modern Middle East. The Israeli victory redrew the political map of the region and created an intractable problem that would remain unresolved for decades.

Israel initially hoped that the destruction and humiliation of the Arab armies would pave the way for diplomatic initiatives, and on June 19 the Israeli cabinet voted to restore the prewar boundaries with Egypt and Syria and to offer the newly occupied Sinai and Golan territories back to their former owners in exchange for peace. The offers were, however, rejected by both Egypt and Syria within days. The Gaza Strip and West Bank proved even more difficult to deal with, as neither Egypt nor Jordan wanted the territories, and their Palestinian populations, back. Furthermore Israel, for security reasons, did not want to return the entire West Bank, as doing so would again put Jordan within miles of Tel Aviv and the Mediterranean. Israel held out hopes that the occupied land could be used to exchange for peace; nonetheless, Israel began settling religious Jews in the newly acquired lands. These settlements would prove to be a major obstacle to peace during negotiations between Israel and the PLO in the late 1980s and 1990s.

The major problem resulting from the Six-Day War was that Israel now occupied the land of more than a million Palestinians: 600,000 living in the West Bank, 70,000 in East Jerusalem, and 350,000 in Gaza (210,000 of whom were refugees, of which 170,000 were living in refugee camps). The occupation awakened Palestinian nationalism and led to protests, graffiti, strikes, and clashes between Palestinians and Israeli soldiers. Such displays remained relatively rare, however, until the outbreak of the first intifada, or uprising, in 1987. The PLO, founded before the war, became the de facto representa-
tive of the Palestinian people and formed the vanguard for a new guerrilla war against Israel, hoping to succeed where the conventional armies of the Arab nations had failed.

At a meeting of the Arab League in September 1967, the Arab states reacted to the war and subsequent occupation by issuing the Khartoum Resolution, whose third paragraph became known as the Three No’s: no peace with Israel, no recognition of Israel, and no negotiations with Israel. In response to the Arab declaration, Israel publicly backed away from the offer to restore prewar boundaries and instead adopted policies of annexation and settlement. The international community stepped into the dispute by passing United Nations Security Council Resolution 242, which became the starting point for all future negotiations surrounding the occupied territories. Resolution 242 required that Israel withdraw from land occupied in 1967 and that the Arab nations end the war against Israel and acknowledge Israel’s right to exist. However, with the exception of Egypt, little progress was made by any side in moving toward peace or resolving the problems of the occupied territories and the Palestinians until the early 1990s.

ARABS

As an ethno-national term, Arabs currently designates the Arabic-speaking population that dominates North Africa and West Asia. The Arabs are considered part of the Semitic peoples, and their migrations out of the Arabian peninsula to the rest of the Middle East in large numbers began in the seventh century. Politically, the term is also applied to the twenty-two member states of the Arab League, whose population in 2005 totaled about 300 million inhabitants, and there were several million more in Europe and North America. The Arab League was originally founded in 1945 to coordinate Arab politics and resolve common issues. The common defining features of an Arab identity include the Arabic language, a sense of shared culture, and similar historical patterns.

In pre-Islamic times, and often in the Qur’an as well, the term Arab, or A’rab, was often reserved for nomadic populations. However, over time the term came to designate all Arabic-speaking peoples. The career of the Arabs in history began with Islam in the seventh century, a coincidence that continues to give rise to much confusion about the relationship between the two. Arab Muslims in fact comprise only about 20 percent of world Muslims. And while the vast majority of Arabs are Muslims, many Arabs belong to various Christian denominations, such as Coptic, Maronite, Orthodox, and Assyrian. Also, until at least 1948 many Arab countries, such as Iraq, Egypt, Morocco, and Syria, housed large Jewish communities that were fully assimilated and largely saw themselves as part of Arab culture. The Arab world also contains many Muslim but non-Arab communities, such as the Kurds in Iraq and Syria and the Imazighen (otherwise known as Berbers) in North Africa.

The rise of Islam in Arabia early in the seventh century provided the first catalyst for unifying the various tribes and communities of the Arabian peninsula into a common, religiously defined state. The Islamic conquests following the death of Muhammad (in 632) were carried out of Arabia in the name of Islam, not Arab nationalism, but they quickly changed the political and demographic makeup of the Middle East by moving Arab populations, and imprinting Arab language and culture, over much of the region. Within less than a century after Muhammad, the domain of Islam stretched as far east as the Indian subcontinent and as far west as the Iberian peninsula. The Arabic language, being the language of the Qur’an (which for Muslims consists of the literal revelations of God) and also the language of the new ruling elites and migrating population groups, spread across immense distances over the next few centuries and came to house greatly refined poetic and cultural traditions. Because the classics of the Hellenic and Roman heritage were translated into Arabic during the Abbasid caliphate, and because the new Arab-centered Muslim civilization patronized all branches of science and philosophy, the Arabic language also became the scholarly lingua franca across vast territories stretching from Central Asia to Iberia. It retained that status throughout the European Middle Ages. In fact, the first authoritative set of rules for Arabic grammar were set down during that period by a Persian scholar, Sibawayh (d. 793).

While presiding over the vast expansion of Islam throughout the region, the Umayyad caliphate, which lasted from 661 to 750 and was seated at Damascus, had a largely Arab ruling elite and sought to exclude non-
Arabs from positions of authority. As Islam became genuinely universal, the Arabs lost monopoly over it. With the rise of the Abbasid caliphate in 750, the Muslim ruling elites became ethnically mixed, reflecting the demographic mix of Muslims themselves. Reflecting the growth in importance of non-Arabs among Muslims, the Abbasids moved the center of political power farther east, establishing Baghdad and making it their capital, thereby replacing Damascus as a Muslim political center.

After more than two centuries of glory, Abbasid rule entered a long period of decline toward the end of the tenth century, even though Islam as a faith continued to spread worldwide. The remnants of the Umayyads, who had established themselves over Iberia, proclaimed a rival caliphate there, and the Fatimids, who subscribed to a version of Shi’ism, soon announced a competing claim to the caliphate after capturing Egypt. The Abbasids also lost much temporal power to successive militaristic Turkish dynasties, notably the Buyids and then the Saljuks. Nonetheless, the Abbasid caliphate was retained in Baghdad as a sort of spiritual symbol for Muslims until the Mongols captured and destroyed the city in 1258.

By that point most Arabs had already become familiar with the pattern of non-Arabs exercising effective rule over them. This pattern was exercised first by other Muslims and then by Western colonialism, and thus lasted well into the twentieth century. Insofar as most governed populations were concerned, there is little evidence that the ethnic origins of the rulers mattered much before Western colonialism. The main cities of what is now called the Arab world were ethnically mixed, although Arabs were usually the majority, and many of them were also religiously mixed, being vital nodes of global and regional trade routes.

The modern idea of Arab nationalism began to emerge in the nineteenth century, when much of the Arab World was still ruled by the Ottoman Empire, centered in Istanbul. The original tracts of Arab nationalist intellectuals show that Arabism was often viewed as compatible with an Islamic identity. The early Arab nationalists, many of whom were Christians, focused on reviving Arab high culture and called for more autonomy and local rule within the Ottoman system. Western models of nationalism clearly influenced these ideas, and within the Ottoman system concurrently informed Turkish nationalism, as it later would be advocated by the Committee of Union and Progress, or the Young Turks. The rise of Young Turks into positions of dominance in the empire shortly before World War I helped deepen Arab hostility to an empire they had lived with for four centuries, since the Young Turks tended to treat the Arab provinces more as colonies of a Turkish center. Moreover, such policies as imposing the Turkish language was at odds with the rising Arab cultural sentiment and the accompanying romanticization of an Arab golden age.

Still, at the beginning of World War I, most Arabs did not appear willing to abandon the empire, even though they had become open to suggestions. Such suggestions came during the war, when the British government persuaded Husayn Bin Ali, the Sherif of Mecca, to declare an Arab rebellion with the promise that the Arabs would gain independence after the defeat of the Ottoman Empire. Arab elites and their peoples did not take a unified stance on the rebellion, but they supported it after it became successful.

The aftermath of the war was a bitter disappointment for most Arabs. Rather than gaining independence, the Arab East was divided up between Britain and France. In addition, Egypt had been under British domination since 1882; most of the rest of north Africa had come under French control at various points during the nineteenth century; Libya was already under Italian control; the gulf region was already designated as a British protectorate. Thus virtually the entire Arab world emerged from World War I as a constellation of colonies of European powers.

Arab countries gained independence at various points over the following few decades, but the usual model of power transfer was from a colonial administration to a narrowly based national elite in each country, often clustered around a monarchy. These elites were preoccupied with survival in power, which usually meant maintaining alliances with their former colonial patrons. The failure of the Arab armies to secure Palestine for Arabs in 1948 undermined that system by vastly exposing the weakness of the new regimes, as well as their iniquity, corruption, subservience to foreign interests, and lack of concern about national interests and common Arab issues. Further, the Palestine debacle highlighted the impotence of a divided Arab World and provided Arabs at large a single great cause around which they could make a unified stand.

During the two decades following the Palestine war of 1948, the era of older postindependence regimes came to an end in most of the Arab World, with the old systems being overthrown in Egypt, Iraq, Syria, Yemen, and Libya, and placed on the defensive in Jordan and Saudi Arabia. The new era was characterized by populism. The most successful figure here was the Egyptian leader Gamal Abdel Nasser. His adoption of pan-Arabism galvanized Arab public opinion everywhere, and his successful challenge to colonial powers by nationalizing the Suez Canal in 1956 and surviving the following tripartite invasion by Britain, France, and Israel, gave Arabs a rare vision of modern success against enemies set on controlling their national wealth and keeping them weak and divided.
The era unleashed by these new regimes also fostered the growth of ideals of social justice, socialism, agrarian reforms, and better distribution of social wealth. However, most of the new ruling elites in places such as Egypt, Syria, Iraq, or Algeria, whose members had to a great extent come from humble social backgrounds, maintained a dictatorial, albeit populist, style of rule. The catastrophic defeat of three Arab armies against Israel in 1967 revealed the continuing vulnerability of the Arabs. It also helped undermine pan-Arab ideals, whose anticolonial, anti-imperialist, and social-justice-oriented content began to be taken up by growing Islamic movements since the mid-1970s. Further undermining pan-Arab ideals were the great disparities among Arab countries caused by oil wealth, with the lion's share going to less populated countries, while the vast majority of Arabs lived in less resourceful, underdeveloped countries.

In spite of the continuing division and lack of coordination among Arab governments, a sense of common Arab identity has been maintained in the public sphere by a media revolution, which started out in the 1990s with the launching of the satellite television station Al Jazeera, based in Qatar. Its success was followed by several imitators and also forced many official governmental media outlets to exhibit more openness so that they could retain their audiences. In recent years satellite dishes have become the most striking feature of the streetscapes of many Arab cities, testifying to an intense interest in uncontrolled information, free dialogue, and a more open public sphere. Common issues include the unresolved question of Palestine and, more recently, of Iraq, which, after undergoing three catastrophic wars in about two decades, again fell under direct foreign control. The new media also foster discussions about other common issues, such as democratization and political reform, the role of Islam in politics and social life, and the status of women. Cultural life in music, the arts, and literature has also remained vibrant, with major figures in each field usually becoming celebrated across the Arab World. Novelists such as Naguib Mahfouz, Abdelrahman Munif, or Ghassan Kanafani are considered important literary figures across the Arab World, as are the poets Mahmoud Darwish or Adnois, for example. Similarly in music it is usual for some singers to attain a pan-Arab appeal in spite of differences in dialects. These include some established singers like Fairuz or Warda, along with more recent talents that are showcased on pan-Arab satellite stations—although none has surpassed the enduring appeal of Umm Kulthum. The notion that there is a common Arab culture and identity remains strong, as does the desire felt among ordinary Arabs for better governance and coordination among Arab countries. There is less conviction, however, that pan-Arab feeling can easily translate into a political union.

ARAFAT, YASIR

1929–2004

Yasir Arafat is best known as chairman of the Palestine Liberation Organization (PLO) and first president of the Palestinian Authority (PA). He was also one of the founding members of Fateh (1959), which would later become the most powerful group within the PLO. More than anything else, Arafat is viewed as one of the patriarchs of the Palestinian national movement. In the 1970s, Arafat also attained the standing of a head of state within the Arab world as a result of two events: First, in 1974, the PLO was recognized as the “official” representative of the Palestinian people by the Arab Summit Conference. Second, in 1976 Palestine was granted full membership into the League of Arab States. In 1994 Arafat was the co-recipient of the Nobel Peace Prize with Israeli Yitzhak Rabin and Shimon Peres in recognition of the successful completion of peace negotiations and the 1993 signing of the Declaration of Principles (Oslo Accords) between Israel and the PLO.

Arafat was trained as an engineer in Egypt and graduated from Cairo University. He then moved to Kuwait, where he worked as a civil engineer. It was in Kuwait that Fateh was founded. For the next forty years, Arafat moved around the region, from Kuwait to Syria to Jordan to Lebanon to Tunisia to Gaza and the West Bank, all in pursuit of his ultimate goal: the formation of a sovereign national homeland for the Palestinian people. Arafat’s complete dedication to the “Palestinian cause,” and the tactics used to further it, often led to tense relations not only with Israeli leaders, but also with his fellow Arab leaders. In fact, it was as a result of some of these tactics that Arafat and his operatives were either jailed (i.e., in Syria) or expelled.

Historians and political commentators have described the tactics used by Arafat and his supporters (either under the banner of Fateh, the PLO, or other organizational names such as Black September) as both guer-
Arbitrage and Arbitrageurs

Arbitrage is a trading strategy that is used to generate a guaranteed profit from a transaction that requires no commitment of capital or risk bearing on the part of the trader. An arbitrageur is a person who engages in this kind of trade to exploit discrepancies in the prices of related assets in different markets. Arbitrageurs profit from the temporary imbalance in the prices of assets that allows them to buy low and sell high in different markets, thereby profiting on the spread between the prices of the same asset in different markets. Arbitrageurs typically use statistical analysis and computer models to identify such discrepancies and to execute trades in a timely manner to take advantage of the profit opportunity before the market adjusts the prices. The practice of arbitrage has been around for centuries, with early examples of arbitrage including the trade in tulips in the Dutch East Indies in the 17th century and the trade in wheat in the grain markets of the United States in the 19th century. Today, arbitrage is a common practice in many financial markets, including the stock market, the bond market, the foreign exchange market, the commodity market, and the futures market. Arbitrageurs play an important role in maintaining the efficiency and integrity of financial markets by ensuring that prices of assets are fair and reflect their true value.
of trading. Arbitrage can be done when equivalent assets or combinations of assets sell for two different prices.

When the opportunity for arbitrage arises, arbitrageurs exploit that opportunity as long as it generates a profit. A simple example of an arbitrage trade would be the simultaneous purchase and sale of the same security in different markets at different prices. Another example would be cross-rate arbitrage transactions in a foreign currency market, in which three currencies are purchased and sold in different markets to exploit mispricing in the cross-exchange rate.

A third example involves the put-call parity relationship in options markets. A put is an option granting the right to sell the underlying asset at a predetermined price (the exercise price) at or before a predetermined date (the maturity date). A call is similar to a put except that it grants the right to buy. With the same underlying asset, exercise price, and maturing date, prices of European-style put options and call options should have a parity relationship in which owning a call option is equivalent to owning a put option, owning the underlying asset, and selling a risk-free bond that matures on the option’s expiration day with a face value equal to the exercise price of the option. If the prices do not conform to put-call parity, an arbitrage strategy can be applied to sell the overpriced instruments and buy the underpriced instruments simultaneously, generating a guaranteed profit that is equal to the amount by which the put or call option is mispriced.

In practice, besides the requisite information, arbitrageurs deal with market imperfections such as transaction costs and limitations on short selling to generate arbitrage profit. If an opportunity is profitable after the full transaction costs have been paid, it is considered pure arbitrage. The arbitrage trade forces the prices of the overpriced assets and the underpriced assets to reach an equilibrium that eventually eliminates the opportunity to generate an arbitrage profit. When there are market imperfections, that equilibrium usually provides boundary conditions that prevent arbitrage opportunities. The principle that no arbitrage opportunities should be available for any significant length of time is one of the elementary principles of derivative pricing. Theoretical boundary conditions of derivative pricing conform to models that assume no arbitrage. That is, the price of a derivative instrument can be modeled on the return of a synthetic portfolio, which is an appropriate combination of the underlying asset and the risk-free asset constructed to replicate the derivative instrument.

Arbitrage profits are examples of abnormal returns and are violations of the principle of market efficiency. In efficient markets arbitrage opportunities are nonexistent or are eliminated quickly. Arbitrage trade facilitates flows of market information. It also forces efficiency in intertemporal resource allocation because arbitrage transactions usually take place over a period of time. The rule of no arbitrage is upheld only if arbitrageurs are vigilant in finding arbitrage opportunities.

**ARCHAEOLOGY**

Broadly defined, archaeology is the study of the human past through the discovery, analysis, and interpretation of the material remains of that past over space and time. The bulk of such material evidence is artifactual, which is anything made or modified by human action. Artifacts encompass everything from the stone tools discarded at Gona in Ethiopia 2.5 million years ago to the trash discarded yesterday. Immovable artifacts, such as hearths or postholes, are called features. Non-artifactual evidence that have cultural significance, such as human, faunal, or botanical remains, are called ecofacts. These material remains tend to co-occur at archaeological sites. Collectively, these traces of the past are referred to as the archaeological record. It is the province of the archaeologist to find, record, and preserve, where possible, the archaeological record in order to identify, analyze, explain, and understand past events and processes. They are also interested in contemporary material culture—ethnographic studies how modern-day people use material culture in their everyday lives. While there are a variety of scientific and other investigative techniques used to reconstruct the past based on this wealth of evidence, archaeological interpretations are constrained by issues of preservation. Not everything discarded in the past will survive in the archaeological record, and thus there will always be gaps in our knowledge.
Archaeologists attempt to bridge these gaps by making use of theoretical models, often based on data provided by ethnographic or ethno-archaeological studies. These theoretical models may vary depending on the training and context of the researcher as archaeology has developed differently in different parts of the world. As will be demonstrated below, archaeology in Europe developed from historical roots and is in some cases regarded as “long-term history.” By contrast, archaeology in the United States falls under the aegis of anthropology and is seen as the study of past cultures.

Archaeology can be characterized as an omni-competent human science as it is concerned with the entire scope of human life from our hominid ancestors to the modern-day industrial age. Archaeological projects are conducted at many different scales. They range from studies of how past peoples used and perceived the landscapes that they inhabited to the re-creation of an individual’s life and death, as exemplified by the work done on mummified or skeletal remains. Archaeologists study long-term change at sites that have been occupied for hundreds if not thousands of years as well as the immediate at “time capsule” sites such as shipwrecks or Pompeii. It is both a science and a humanity. Many archaeologists also have sub-specializations in the natural sciences such as zoology, botany, and chemistry while others make use of anthropological and historical methodologies and sources.

**DOING ARCHAEOLOGY**

Archaeologists make use of a diverse methodology. While the most important task is to place finds within a chronological and spatial framework, techniques differ depending on the scale at which the archaeologist is working. The upper end of such a scale is that of the identification of sites within a region. Many finds of archaeological sites and artifacts are still the result of accidental discovery by non-archaeologists, but there are a wide range of survey techniques in existence that allow for the location of archaeological sites within the landscape. These range from systematic pedestrian surveys of a region in search of surface traces to the use of aerial photography and other remote sensing techniques (including ground-penetrating radar, bowsing, and magnetometers) to locate buried remains. Archaeologists often cannot afford either the time or money to achieve total coverage of a region and may thus use sampling techniques designed to either maximize site location or to statistically reflect the occurrence of sites within a region.

Once a site has been located and recorded, the material remains at that site can be further explored and their relationship to one another determined by excavation. Excavation can be conducted either horizontally (clearing excavations) or vertically (penetrating excavations) depending on the nature of the site and the kinds of questions that the researcher is attempting to answer. Most excavation projects will include a mixture of both. Excavation involves the physical destruction of the site and the removal of artifacts and other remains and is thus guided by rigorous standards of recording and fieldwork practice. Most importantly, the context of finds is recorded so that their position in the site and their relationship to one another can be reconstructed once their original provenance has been destroyed.

Context is also crucial for establishing either the relative or absolute age of archaeological remains. Relative dates do not allow a specific age to be assigned to an archaeological find or excavation layer; rather they indicate the age of finds relative to one another. Relative dating was paramount until post–World War I advances resulted in a wide range of chemical and other dating techniques that allow absolute or calendar dates to be assigned to artifacts and sites. Foremost among these are radiocarbon, uranium series, potassium-argon, and thermo-luminescence dating. The most widely used of these is radiocarbon dating, which is used to date organic remains and can provide fairly reliable dates back to forty thousand years ago. The other chemical dating methods mentioned above can be used to date inorganic remains and offer a much greater chronological depth. Archaeologists working in more recent time periods can also use documents or other written evidence to date sites.

Once excavated, artifacts are sorted, classified, and analyzed in an archaeological laboratory. This analysis allows the archaeologist to create order out of a mass of data; to summarize many individual artifacts by identifying their shared characteristics; and to define the variability present within an archaeological assemblage. There are many debates about the best way to classify artifacts. They are mostly analyzed in terms of formal, stylistic, and technological attributes. Philosophically, there is a question as to whether or not the categories of artifacts that archaeologists devise reflect the emic order (items analyzed in terms of their role as structural units in a system) created by the people who produced the artifacts or if they are etic (items analyzed without consideration of their role in a system), artificial categories imposed by the archaeologist. Most archaeologists, however, recognize that the best classification systems are a combination of the two.

The suite of techniques that we associate with modern, professional archaeology did not, of course, emerge fully fledged but developed over the course of more than a century. While many societies over the centuries displayed an interest in the material remains of the past and there are even instances of past societies excavating to uncover those remains, it was not until the nineteenth century that archaeology truly became a scientific
discipline. Archaeology's roots lie in two disparate contexts: the development of classical studies from the 1500s onward and subsequent discoveries in various parts of the world; and the gradual recognition of the true age of the earth in the eighteenth and nineteenth centuries.

CLASSICAL BEGINNINGS
The fifteenth-century Renaissance in western Europe prompted interest in the Greek and Roman civilizations, particularly as their art and architecture were still highly visible. The buried Roman cities of Pompeii and Herculaneum were rediscovered in the 1700s and were excavated for art and antiquities. The foundation for art history and subsequently much of classical archaeology was laid in 1764 by the publication of Johann J. Winckelmann's History of Ancient Art (1764), in which he contextualized the art's production and set out the first systematic chronology for classical remains. Early excavation of these classical sites was by no means methodical. Smaller artifacts and “unimportant” structures were destroyed during the search for highly desirable works of art. It was these classical studies that provided a model for the development of Egyptology and Assyriology, which themselves evolved within a larger context of European imperial expansion.

Egyptology developed as a direct result of Napoleon Bonaparte's (1769–1821) invasion of Egypt in 1798. Accompanying the French army on this expedition was a Commission of Arts and Sciences that published multiple volumes of Description de l'Egypte from 1809 onward. The invasion also led to the accidental discovery of the Rosetta Stone, which featured the same passage written in hieroglyphs, Demotic (a cursive form of hieroglyphs), and Greek, thus enabling Jean François Champollion to finally decipher the hieroglyphic script in 1822. At this time there was widespread looting by both locals and foreigners in search of treasure for sale or collection, including not only easily transportable artifacts but also the wholesale removal of large monuments, such as Giovanni Belzoni's 1816 removal of the seven and a quarter ton granite head and torso of Ramesses II from Thebes to Alexandria. Belzoni, and others like him, worked as agents for the European elite and were involved in the discovery and excavation of many sites in Egypt. At this time there was little interest on the part of Egypt's rulers in preserving or investigating their past through the preservation of the remains of that past. They thus sanctioned the activities of many of the European agents at work in the country. It was not until Frenchman Auguste Mariette was appointed as the director-general of the Antiquities Service in 1858 that the sanctioned plunder and export of Egyptian antiquities ended.

There was widespread interest in the Egyptian past and many expeditions were funded, but the systematic excavation and recording of Egypt's archaeological past only began with William Matthew Flinders Petrie (1853–1942) in the 1880s. Petrie emphasized the careful recording of all artifact material recovered in the excavations as well as the full publication thereof. Further, he developed the first typological sequence dating (based on ceramic jars recovered from graves) to be used in Egypt. His work laid the foundation for other archaeologists such as Howard Carter (1874–1939) who, funded by his patron Lord Carnarvon, discovered and carefully excavated the sealed tomb of Tutankhamun in 1922. As all other tombs discovered in the Valley of Kings had been looted, this find remains one of the most spectacular Egyptian discoveries.

As European governments began to take a political interest in places like Egypt and the Near and Middle East, historical and archaeological scholars followed suit. These areas were of especial interest to the European public because of their link to places mentioned in the Bible. Unlike in Egypt, however, there were few impressive structures that had survived the ravages of time in Asia Minor, Syria, Palestine, Mesopotamia, or Persia. Rather, explorers in the region reported the existence of large mounds that local tradition held to be biblical locations such as Babylon and Nineveh.

The first systematic work on mounds in Mesopotamia was carried out by the French consul in Mosul, Paul Emile Botta, who had previous experience in Egypt. The French government funded his excavations and paid for the transport of finds to Paris. Further research was also carried out by Henry Layard, an Englishman who is best known for his work at Nimrud. Wholesale excavation and exportation of finds was only halted after World War I (1914–1918) when much of the Near East was placed under French or British control. Museums were established, as were departments of antiquity and stratigraphic (layered) excavation, and the recording of all finds became the new standard. This standard was exemplified in Leonard Woolley's excavations at the site of Ur in the 1920s.

While these major discoveries were being made in Egypt and the Near East, the traces of civilizations of equal complexity were being discovered in the Americas. Monumental ruins were not common in North America, but large earthen mounds were often remarked upon. The question of who built these mounds—the ancestors of Native Americans or a lost race of moundbuilders—swiftly became one of the most contentious issues in American archaeology and remained so until the end of the nineteenth century. In 1781 Thomas Jefferson became the first person known to have used the principle of...
stratigraphy to interpret archaeological remains during his excavation of a mound on his Monticello estate. Meanwhile in South America, Antonio del Rio “discovered” the Mayan ruins of Palenque in 1786. It was not until 1896, however, that a stratigraphic excavation was conducted on that continent when Max Uhle started working at Pachacamac in Peru. Peru also yielded the well-preserved Inca site of Macchu Picchu, which was located by Hiram Bingham in 1911.

ROOTS OF PREHISTORIC ARCHAEOLOGY

While discoveries were continuing apace in the eighteenth and nineteenth centuries, intellectual trends in Europe were laying the groundwork for an archaeology of Europe’s prehistory. These trends eventually led to the emergence of archaeology as an academic discipline rather than merely the occupation of adventurers and collectors, and they include the development of typological sequences, the use of stratigraphy, and the acceptance of the principles of uniformitarianism, all of which center around the key issue of chronology.

Up until the seventeenth and eighteenth centuries, it was widely accepted, based on biblical chronology, that the earth was no older than six thousand years. Several discoveries of stone tools in association with the bones of extinct animals by individuals such as John Frere in 1797 and Jacques Boucher de Crèvecœur de Perthes in 1837 demonstrated, however, that the earth and human existence on it was much older than had previously been believed. Two theories had been advanced to explain these and other geological and paleontological finds. Catastrophism, advocated by scientists such as Georges Cuvier, was the notion that the earth had been periodically destroyed numerous times in the past, after which a new creation would occur. Uniformitarianism, put forward by geologist Charles Lyell in his Principles of Geology, Being an Attempt to Explain the Former Changes of the Earth Surface by Reference to Causes Now in Operation ([1830–1833] 1969), was the theory that the earth had been formed over a long period of time by a series of geological processes that are still observable in the contemporary world. It was this latter theory, in addition to the increasing fossil evidence, that contributed to the theory of biological evolution and the publication of Charles Darwin’s Origin of Species by Means of Natural Selection, or The Preservation of Favoured Races in the Struggle for Life ([1859] 1998). Lyell’s work also gifted archaeology with the concept of stratigraphy, and thus the law of superposition, which states that stratigraphic layers are arranged chronologically, with the oldest layers at the bottom and the younger layers at the top, unless disturbed by later processes. This is the foundation for all interpretations of stratified archaeological deposits.

Even before the age of the earth had become widely accepted, chronological sequences for archaeological material, independent of written records, were being developed. One of the first was that of Danish scholar, Christian Thomsen (1788–1865), who was given the task of cataloguing and preparing for exhibition a collection of antiquities in 1816. He used the Three Age System, subdividing the prehistoric period into stone, bronze, and iron. While the idea was not new, Thomsen was the first to apply it to a large artifactual assemblage. He solved the problem of knowing which finds should be placed in which age by using “closed finds,” artifacts that had been buried together in hoards and graves. By delineating which types and styles of artifacts were found or not found together he was able to work out a stylistic typology with chronological significance. This kind of stylistic ordering is known as seriation and is an important relative dating technique. Stratigraphic excavations of Danish burial mounds conducted by Jens Worsaae, a student of Thomsen, supported this sequence. The notion of technological progress, coupled with the ideas of biological evolution, gave rise to the unilineal cultural evolution of E. B. Tylor and L. H. Morgan and was expounded in John Lubbock’s archaeological text Pre-historic Times, as Illustrated by Ancient Remains, and the Manners and Customs of Modern Savages (1865) 1971).

There were further major developments in archaeological methodology at the end of the nineteenth and beginning of the twentieth centuries. Oscar Montelius refined Thomsen’s seriation method of dating using a typological approach, while between 1880 and 1900, Augustus Henry Lane-Fox Pitt Rivers, a retired British general, conducted several excavations of barrows on his estate and developed the standards for excavation, recording, and publication associated with modern-day archaeology. These included the recording of all finds including those not directly related to the research questions being asked, as well as the recognition of the chronological value of even unimportant finds (potsherds, for example) if their context was correctly recorded. Later, it was a student of Pitt Rivers, R. E. M. Wheeler, who developed the grid method of excavation and, in the 1940s, went on to revolutionize the archaeology of the Indian subcontinent with his work at Mohenjodaro and other sites.

THE CULTURE-HISTORICAL APPROACH

The unilineal evolution of the nineteenth century was replaced in the early twentieth century by an interest in historical questions. This shift from an evolutionary perspective to culture-history resulted in an increased empha-
sis on descriptions of past cultures. In Europe there was a desire to discover how particular peoples developed in the past in order to promote national unity. In the United States, where archaeology was regarded as part of anthropology, there was an increased emphasis on data collection as the foundation for the development and testing of theory and explanations, in addition to chronologies.

Culture history, as a theoretical approach, has a normative view of culture. Basically it holds that cultures are composed of shared norms and values and that their members share a particular worldview. Artifacts are therefore seen as expressions of the shared norms and values of any given culture. This approach emphasized data collection, which allowed for the construction of site and regional chronologies. The results of these endeavors were often represented in a time-space grid. In the cultural historical view, change is most often attributed to the action of outside forces, most commonly migration and diffusion, or environmental change.

In the United States this approach was pioneered and applied par excellence by Alfred V. Kidder, who was also the first archaeologist to use the stratigraphic method on a large scale in the Southwest. The first scholar to systematically apply it to archaeological data in Europe was Gustav Kossina in his book *Origin of the Germans* (1911). Kossina argued that cultural boundaries (as reflected in material culture) were also indicative of ethnic boundaries. His work was extremely nationalistic and was later used by the Nazis in the Socialist education system. By tracing the migrations of the Indo-European people and demonstrating the supposed racial purity of the German people, he argued that the Germans were the true heirs of the Indo-Europeans and, by extension, were the true heirs of Europe. Archaeology was thus also used to establish historical rights to territory. Kossina’s work had little impact outside of Germany and while British archaeologists recognized the importance of repeated invasions and migrations, they did not rigorously apply the culture concept until the appearance of V. Gordon Childe’s *The Dawn of European Civilization* (1925; 1958), after which the “archaeological culture” became central to European archaeology.

**COLONIAL ARCHAEOLOGY**

By the end of the nineteenth and beginning of the twentieth century, archaeological fieldwork was also increasingly conducted in colonial contexts. While much of this archaeology was essentially cultural-historical in approach and method, the situation in the colonial arena was complicated by the sociopolitical relations that existed between colonized and colonizer. Bruce Trigger in his 1984 work offers a definition of colonialist archaeology as comprising that archaeology which developed either in countries “whose native population was wholly replaced or overwhelmed by European settlement or in ones where Europeans remained politically and economically dominant for a considerable period of time” (p. 360). Specifically, an archaeology as practiced by “a colonising population that had no historical ties with the peoples whose past they were studying.” Tied up as it is in land and heritage issues as well as its commentary on the supposed political or social sophistication of the cultures being studied, archaeology in these places had an increasingly political dimension.

This was especially the case in the southern African context. At sites such as Great Zimbabwe, it was denied that the ancestors of local people could have been the builders and inhabitants of what was clearly an advanced civilization. As with the myth of the moundbuilders in the United States, this made it easier to claim a civilizing mission and to take ownership of the land. Great Zimbabwe represents possibly one of the most famous examples of the misuse of the past to suit political purposes in the present. The racist theories of Zimbabwe’s past have not been easily laid to rest. Claims that it was the place of King Solomon’s mines or was built (variously) by the Queen of Sheba, the Sabaeans, or the Phoenicians were still being disseminated well into the 1970s.

**PROCESSUAL ARCHAEOLOGY**

By the 1940s some North American scholars were becoming dissatisfied with the shortcomings of culture history, which was severely hampered by a lack of absolute dating techniques that would allow the refinement of chronologies. Walter Taylor called for a conjunctive approach to the past in *A Study of Archaeology* (1948; 1983), advocating that artifacts should be looked at in their broader social contexts. His book did not spark a revolution, but in the 1960s a series of articles written by a young Lewis Binford (1962, 1967) did. Influenced by the 1950s neo-evolutionary anthropology of Julian Steward and Leslie White, Binford and his fellow “New Archaeologists” criticized the normative view of culture as inadequate in that it did not address how people interacted with their environments or how material culture was used as an adaptive tool in that environment. They emphasized the relationship of archaeology to anthropology and stressed the need to go beyond description to explanation. Culture history was seen as too particularistic and its practitioners as not being explicit enough about their research objectives, methods, and expectations.

The school of thought and methodologies for research espoused by the New Archaeology have come to be more generally known as processualism. Processualism, as an approach to archaeology, is heavily influenced by scientific positivism. It is based on a belief in “objective sci-
ence” and aimed to test archaeological propositions against data in order to answer anthropological questions and to deliver broad generalizations—law-like statements—about human behavior. While the most famous processualists are undoubtedly American scholars such as Lewis Binford and Kent Flannery, many of the ideas espoused by them were also taken up by British archaeologists including Colin Renfrew. While Renfrew did not wholeheartedly embrace all aspects of processualism such as the search for law-like generalizations, its systemic approach to the study of culture and the new methodologies proved attractive.

The New Archaeology was characterized by a battery of new methods, techniques, and aids fostered by advances in scientific dating methods. The most important of these was the development of radiocarbon dating, which made internal development more likely than migration and diffusion as an explanation of change. It also meant that archaeologists were finally free to focus on broader questions of cultural and social significance rather than on the development of regional chronologies. Other scientific advances included the use of computers and, in the study of the environment, pollen diagrams and soil geomorphology. The application of these to archaeology necessitated increasing specialization on the part of archaeologists; and increased funding from bodies such as the National Science Foundation led to the scientificization of archaeology, especially in the United States.

Fieldwork also became more rigorous and standardized. This was partly a response to the expansion of cultural resource management, which meant an increased need for systematic control and monitoring. Most processual archaeology has strong environmental overtones and thus new field and research methods were developed to accommodate those questions. Regional approaches—the analysis of sites in their settlement systems and environments—were developed, as well as new survey, sampling, and screening techniques to recover the most environmental evidence possible.

The New Archaeology changed the way in which archaeological research projects were administered and carried out. Advocates of this school adopted a formalized methodology that had hypothesis testing as its central emphasis. Archaeologists were expected to clearly and explicitly state the conditions and expectations of their hypotheses. Models employed by processual archaeologists include systems models, cultural ecological models, and multilinear cultural evolution models. One of the best-known case studies is Kent Flannery’s use of systems theory to explain the increasing reliance on maize agriculture in Mesoamerica, which he detailed in 1968.

One of the most important aspects of processualism was the desire for an objective evaluation of ideas and research designs. To achieve this Binford developed Middle Range, or bridging, theory. This solved one of the primary problems facing archaeologists, that of inference, the linking of the (observable) present with the (unobservable) past. In order to understand what happened in the past, a way had to be found to link the dynamics of human action in the past with the static material traces of those activities in the present. Binford felt that archaeologists should observe the processes that give rise to the patterns and their variations, discernible in the archaeological record. This interest of Binford’s in actualistic studies led to an increased focus on experimental- and ethno-archaeology.

The greatest contribution of processualism was methodological, in the sense that issues of sampling, inference, and research design were paramount. These were of course closely linked to the increased use of scientific techniques in archaeological fieldwork and analysis. The second contribution is seen as the shift away from description to explanation, particularly the notion of culture as adaptive and the interconnectedness of social and ecological variables. It also moved archaeology forward in the consideration of long-term processes. While processualism was seen as advancing research in some areas, it was also seen as retarding research into others. While significant advances were made in the study of prehistoric economies, topics such as the role of the individual decision-making, conflict and negotiation between different social groups, and prehistoric ideology were neglected while certain actors/interest groups were excluded from analysis. Many of these arise directly from the processual focus on entire systems and the overriding view that the environment plays the most important role in bringing about change.

POST-PROCESSUALISM

In the light of these limitations, by the late 1970s and early 1980s some archaeologists were arguing that while processual archaeology aimed to explain the past, it could not understand it. In Reading the Past (1986) Ian Hodder argued that material culture and past events had to be understood with reference to people’s attitudes and beliefs, not just their adaptation to an external environment and, further, that archaeological remains could be “read” as a “text.” Similarly, Michael Shanks and Christopher Tilley critiqued the scientific focus of processual archaeology in Re-constructing Archaeology (1987), arguing that archaeologists have to be critical of the context in which archaeological interpretations of the past are produced and that multiple interpretations of the past are valid. This critical approach has also been adopted by feminist archaeologists, such as Margaret Conkey and Janet Spector (1984), who have highlighted in “Archaeology
and the Study of Gender” the androcentric bias in representations of the past and the practice of archaeology.

While post-processual and cognitive archaeology is an umbrella term incorporating many different theoretical approaches, it is characterized by its cognitive—as opposed to normative or adaptive—view of culture. Thus culture is seen as being actively constructed and reworked by individuals in order to fit the context of their own lives. The various approaches included within post-processualism can be divided into three different categories. The first deals with approaches that have at their base a concern with structure, such as structuralism, cognitive approaches, and Marxism. Second is contextual archaeology, which views material culture as a text that can be read. The third incorporates a variety of approaches that seek to offer alternative perspectives on the world and the way in which archaeological results are communicated, such as phenomenology, feminism, and postmodernism. Post-processual approaches have been especially embraced by historical archaeologists, who also have written documents to draw on. James Deetz, for example, used structuralism in his seminal study *In Small Things Forgotten* (1977) to explore the changing worldview of North American immigrants while Mark Leone has adopted a critical approach in his study of ideology in Annapolis.

Undoubtedly the post-processual critique has made contributions to the discipline. It has moved archaeology away from modeling the environment as the prime mover in past human societies and has added greatly to our ability to understand the past. The political nature of the study of the past and the sociopolitical context of the researcher have also been problematized. More attention is now paid to the way in which archaeologists interact with contemporary groups that have a stakehold in the past and how that past is represented. It remains, however, a largely Anglo-American phenomenon and has hardly affected archaeology on the European continent.

**AN EVOLVING SCIENCE**

Since the 1980s archaeology has been characterized by a wide diversity of approaches that draw on a range of theory from other social sciences including anthropology, sociology, geography, history, and political science. Like their counterparts, archaeologists make use of practice theory, agency theory, political economy, cultural ecology, world systems theory, and so on. Many times these viewpoints are combined or applied in interesting new ways to the archaeological record.

Archaeology is a constantly evolving discipline. New fields of study are always being created. Since the 1950s sub-disciplines such as landscape, historical (post-medieval), and industrial archaeology have grown rapidly. Further archaeological discoveries and fine-grained analy-

ARCHITECTURE

Architecture is the art and science of building the human environment. Because that environment is meant to enclose, enhance, and shape human activity, architecture thus extends beyond abstract issues of formal geometrical design and structural science into a far broader social dimension. As Winston Churchill is famous for saying to Parliament in 1943: “First we shape our buildings, and then our buildings shape us.”

Exactly when the conscious, deliberate shaping of the human environment began defies dating, since the earliest structures most likely were made of organic materials that quickly returned to earth. Archaeological evidence discovered near Marseille, France, however, revealed repeated construction of wood-framed dwellings dating back as far as 300,000 to 400,000 years ago, and several skin coverings and wooden house frames from 13,500 years ago were surprisingly preserved at a Chilean site called Monte Verde. The well-known stone structures of megalithic Europe date to 6,000 years ago, but it is significant that these were almost universally built for ceremonial or religious purposes, while the construction of dwellings apparently still relied on vegetable and animal materials long since vanished. Hence, the first intentionally permanent architecture was shaped for the most fundamental of social communal purposes—to bring a sense of visible order to the cosmos and to provide a link to the dead.

Architecture is a decidedly social activity, for it involves the interactions of many individuals, beginning with the patron—individual, committee, or organization—who calls a building into being. The architect and assistants, or architectural firm, then translate the client's wishes into abstracted drawings and other construction documents that are used in turn by an army of construction specialists to fabricate the final product. At every step of this process, social exchanges, discussions, and negotiations are required to adjust the design to changing needs and costs. This multidisciplinary social process involves large numbers of people specializing in many occupations, such as drawing and computer design, materials acquisition, preparing written specifications, scheduling construction, arranging construction materials, assembling the prepared materials, and applying the interior finishes, among many others. For the most complex buildings, additional management specialists are required to ensure that materials and subassemblies arrive at the building site with optimal timing to prevent costly delays.

As a social art, architecture is subject to a range of controlling forces to ensure public safety. In ancient Rome, huge privately financed urban apartment blocks, called insulae, sometimes were so shoddily built that they collapsed. With the establishment of a firmer centralized authority during the Roman Empire, regulations were enforced to curb the worst of these building shortcuts. Later, during the seventeenth and eighteenth centuries, governing authorities in France and Britain similarly instituted building regulations to reduce the spread of urban fires. In the United States, following disastrous fires in Boston and Chicago in the late nineteenth century, building codes and regulations were instituted in larger cities. To ensure general public safety, nearly every community now has zoning regulations and building codes controlling where types of buildings can be located and governing density as well as engineering requirements of design.
and durability of building materials. These regulations apply equally to commercial and governmental buildings, as well as to private residences.

Making architecture involves the shaping of space in a way reached by no other art. Whether fully enclosed or an open external area, architectural space has several different properties. Initially designed to accommodate some function of human activity, this space is definable as square feet or meters. If the space is enclosed by glass, then the user’s view extends beyond the physically enclosed space, and this larger reach constitutes perceptual space less easily quantified. If some substantial object is permanently fixed in that space—a large table, for example—the physical presence of that object emphatically conditions human use of the space, giving definition to the social parameters of behavioral space.

Beyond these three-dimensional aspects, another important spatial quality is the distance members of a particular species place between themselves. This strong determinant of social behavior, called personal space, can be seen in the way birds space themselves along a telephone wire. Seemingly genetically programmed, impinging upon personal space may produce socially aberrant behavior. Among humans, however, Edward T. Hall notes in *The Hidden Dimension* (1966) that personal space seems to be significantly determined by culture in addition to any fixed internal programming.

Making places for human use extends from the design of a single room and its interior furnishings in ever-increasing scales: from a small building to a large multi-story office or institutional structure, to a group of interconnected buildings such as a college campus, to an urban neighborhood, even to the planned organization and pattern of use of a region. Architectural design involves not only physical structures but also the landscape in which the buildings are placed.

### MEANING IN ARCHITECTURE

Buildings embody wishes and aspirations on several levels, beginning with the desires of the client. Typically, images a client might envision for a building are part of a general collection of accepted communal formal qualities, evolved over time and called by a style name. These stylistic qualities are understood by most of the community and symbolize its values at any given time.

This concept is the iconography of a particular architectural style. To later historians, additional layers of meaning might be discernible, but these interpretations may not have been part of the consciousness of the original builders. This more embracing concept is the iconology of a time period.

### THE SOCIAL FUNCTION OF ARCHITECTURE

In sketching the general iconological content of past architecture, one might make several observations:

- that ancient Greek architecture, particularly temples, represented humans striving to achieve the highest level of excellence in construction;
- that ancient Roman architecture borrowed details from Grecian architecture for use in buildings of vast scale devoted to public purposes;
- that the most important medieval architecture served to reinforce human religious life in anticipation of an eternity in heaven;
- that Renaissance architecture sought to fuse this inherited religious meaning with a renewed appreciation of the geometric logic of classical architecture; and
- that Baroque architecture endeavored to appeal to emotions to enhance religious mysticism (in the ecclesiastical realm) or to make a political impression through magnificence or vastness of scale (in the aristocratic realm).

Architects of the nineteenth century struggled to master new industrial technologies while attempting to understand the enormously rich and complex history of architecture around globe.

What changed in the early twentieth century was an added layer of social utopianism, an outgrowth of the Arts and Crafts movement in England. Through the exploitation of industrial production processes, and using industrial materials such as concrete, steel, and glass, architects were challenged to devise a radically new architectural style that would eliminate slum housing. Moreover, this new millennial architecture was to be shaped by an idealistic view of the way things should be (at least in the eyes of the architects and theorists), rather than shaped by the way things actually were. The resulting new communities were to provide fresh air, clean water, and open space in the belief that these transformations would permanently improve society. Architect and polemicist Charles-Édouard Jenneret (who called himself Le Corbusier) declared in his 1923 *Vers une Architecture* that it was either this new architecture or social revolution. He even suggested the creation of a normative type—one building type for all people everywhere. Begun in Europe at the dawn of the twentieth century, the new architecture became public policy in the 1920s and 1930s, with more limited application in the United States. Although this social utopianism was well intended, it often fell short of the objective. It may have been supremely utilitarian, but
as Hannah Arendt would observe in her 1958 *The Human Condition*, utility established as meaning generates meaninglessness.

The perceived lack of referential meaning in the International Modern style (as it came to be known by mid-twentieth century) led to a reaction by a new generation of architects, particularly Robert Venturi and Denise Scott-Brown in the United States. Beginning with the use of broadly and whimsically altered historic details, postmodern architecture appeared in the mid-1960s, entering the professional mainstream by the end of the 1980s and extending worldwide by the 1990s. In referencing the past, postmodernism also validated reexamination of traditional regional architectural styles around the globe. Architects in Hungary, Egypt, Saudi Arabia, Sri Lanka, and scores of other nations began to draw inspiration from their own ancient regional traditions in new buildings of wholly original design and construction; such architecture proved rich in meaning to its users. Architecture in the late twentieth century was viewed once again as capable of being a powerful element in how people envision themselves in time and place.

**NEW ARCHITECTURAL CONSIDERATIONS FOR THE TWENTY-FIRST CENTURY**

The end of the twentieth century was marked by the emergence of certain mega-architects identified by their unique building forms. Most notable was Frank Gehry, known for his multiply curved, metal-clad, irregularly shaped “swoosh” buildings. Exploitation of computer-aided design has rendered such complex building forms more cost effective, marking a dramatic change in the imagining and construction of buildings and doing away with traditional drafting instruments largely unaltered for centuries. The unfolding effect of this fundamental change in design methodology will shape twenty-first century architecture.

An equally significant shift in the nature of the discipline is the emergence of women in a field dominated for centuries by men. Women began to make important contributions beginning at the dawn of the twentieth century, but their names were seldom widely known and their numbers were few. This advent of women as major players in the discipline was vividly demonstrated by the award of the prestigious international Pritzker Architecture Prize to Zaha Hadid in 2003.

Perhaps more significant for Earth’s future is the movement toward sustainable “green” architecture. The traditional energy-consuming methods of making construction materials—toxic in themselves and leaving toxic residue from their manufacture—resulted in buildings that, once completed, further consumed prodigious amounts of energy for lighting, heating, cooling, and ventilating. Nowhere was this old-style architecture more evident than in the thin-walled modernist glass-sheathed boxes of the mid-twentieth century. In contrast, the emerging philosophy of sustainable green architecture promotes using less toxic materials and forming buildings in ways that allow them to work with, rather than against, nature. For example, windows can be shaded by calculating orientation and latitude to prevent internal solar heat gain, and buildings may be cooled in part by facilitating natural ventilation, practices of architect Ken Yeang. The future social implications of such a design approach, especially in the reduction of long-term operating costs, are enormous.

**BIBLIOGRAPHY**

*Leland M. Roth*
Arendt, Hannah
1906–1975

A political theorist endowed with a flair for grand historical generalization, Hannah Arendt focused contemporary thought, particularly in scholarly circles, on the novelty of the tyranny that afflicted Europe in the twentieth century. Her most influential book, The Origins of Totalitarianism, emphasized the parallels between the Third Reich under Adolf Hitler and the Soviet Union under Joseph Stalin.

Arendt was born on October 14, 1906, to middle-class Jewish parents in Hanover, Germany. After studying theology and philosophy at the University of Marburg, she specialized in philosophy at the University of Heidelberg. As the National Socialists drew closer to power, she became a political activist and, beginning in 1933, helped German Zionists publicize the plight of the victims of Nazism. For the remainder of the decade, Arendt lived in Paris, aiding in the efforts to relocate German Jewish children to Palestine. In 1940 she married a former communist, Heinrich Blücher; later that year they were interned in southern France along with other stateless Germans and Jews after the Nazi invasion. Arendt and her husband landed in the United States in May 1941. While living in New York City during and after World War II, Arendt wrote The Origins of Totalitarianism, published in 1951, the year she secured U.S. citizenship.

No book traced more insightfully the steps that Hitler and Stalin took toward creating their distinctively modern despotisms, nor calculated more evocatively how grievously wounded civilization had become as a result of the concentration camps, the slave labor camps, the extermination camps. In exposing the operations of “radical evil,” she demonstrated that with the superfluity of life toward which it aimed, totalitarianism marked a crucial discontinuity in the very notion of what it has meant to be human. The Origins of Totalitarianism asserted that the hell that medieval visionaries could only imagine had been put into practice in Auschwitz and Treblinka and in the Gulag Archipelago.

Her book exerted its greatest impact during the bleakest phase of the cold war, because of Arendt’s insistence upon the resemblances between Nazi Germany and Stalinist Russia. Such claims also engendered doubt among scholars, who noted her limited access to Soviet sources. Nevertheless, her emphasis on the precariousness of European Jewry while Enlightenment ideals of human rights were collapsing, plus her argument that Nazism was conducting two wars—one against the Allies, the other against the Jewish people—became truisms in the history of the Holocaust.

In 1963 came a sequel of sorts, and her most controversial work. Eichmann in Jerusalem: A Report on the Banality of Evil did not portray the S.S. lieutenant colonel who had directed the transportation of Jews to their deaths as an anti-Semitic fanatic. He was instead an energetic organization man whose primary attribute was a sense of duty. Nonetheless, her book endorsed the Israeli verdict that he be hanged for his crimes. Arendt’s view that Eichmann’s iniquity did not stem from sadistic impulses to orchestrate genocide, but was the result rather of sheer thoughtlessness (a failure to think through what he was doing), led her back in the final phase of her career to the formal philosophical approaches that had marked her German education. Arendt died in New York City on December 4, 1975.

Aristocracy

The term aristocracy derives from the Greek words aristas and kratos, meaning “rule by the best.” In denoting hierarchy and social differentiation, aristocracy has often been used synonymously with elites or oligarchy. More broadly, the term has been used in modern formulations such as “America’s aristocracy” to denote a plutocracy of wealth and privilege in the United States, or as “labour aristocracy” in the United Kingdom to refer to a privileged stratum of skilled workers within the nineteenth-century working class. Indeed, its modern usage is so broad that many commentators have concluded that aristocracy is now impossible to define.

The aristocracy in preindustrial European states combined specific economic, social, and political characteristics that differentiated it from other social strata at the time, and from subsequent notions of aristocracy in industrial and postindustrial societies. For a period of over five hundred years, before the rapid spread of industrialization in the nineteenth century, predominantly agrarian societies in Europe were structured in feudal hierarchies and governed by monarchs in varying alliances with landed aristocrats. In these hierarchies, aristocrats were differentiated from monarchs in one, upward direction,
and from gentry, merchants, and peasants in the opposite
direction.
In economic terms, aristocracy in preindustrial soci-
eties was defined in relationship to the land. Initially in
feudal systems, monarchs granted feudal lords the rights
to income from large estates or manors in return for mil-
tary support and local administration of justice. Thus,
aristocrats derived their income primarily from land,
either directly through the extraction of services and dues
from peasants, or, latterly, indirectly through sharecrop-
ping contracts or lease-renting arrangements with small
farmers.

The economic differentiation of the aristocracy was
reinforced by social distinctiveness. Monarchs conferred
not only economic rewards but also status rewards in the
form of titles. Although titles were not an exact indicator
of membership in the aristocracy, they were, when com-
bined with land ownership, the most effective defining
characteristic of the aristocracy. Noble rank reinforced
notions of social exclusivity, and even among the aristoc-
Tacy there was an internal hierarchy of titles that distin-
guished landed magnates from lesser nobility.

The aristocracy’s combined economic and social
dominance was sustained over centuries through inheri-
tance laws based on primogeniture (where succession
passes to the firstborn son). In this manner, the indivi-
dibility and continuity of landed estates was secured and the
social status of titular rank was passed from one male
generation to the next.

A deliberate cult of ostentation characterized the
lifestyle of most European aristocrats. “Living nobly”
entailed architectural recognition in the construction of
grand country residences and palatial dwellings in capital
cities; cultural recognition in the patronage of the arts and
music; fashionable recognition in elaborate dress and tailor-
ing; and educational recognition in, for example, the value
placed upon multilingualism by European aristocrats.

Political power was closely associated with the eco-
nomic and social power of the aristocracy. Nonetheless,
there were wide variations in the political relationships
between monarch and aristocracy from one country to the
next. By the seventeenth and eighteenth centuries, there
were marked contrasts between France, where the aristoc-
Tacy was politically enfeebled, and England, where the
landed aristocracy effectively restricted monarchical power
through representation in Parliament. Eventually, with the
transition to industrial capitalist economies, the political,
social, and economic ascendency of the aristocracy was
eroded in all European states. Even in the twenty-first cen-
tury, however, residues of aristocratic status and wealth
can still be traced in many European countries.

ARISTOTLE
384–322 BCE
Aristotle was born near the Greek village of Stagira. While
he was still a young man, this area came under the control
of the kingdom of Macedonia. Aristotle’s father was a
physician in the royal Macedonian court, which led to the
son’s early interest in biology and, later, to his becoming
the tutor of Alexander the Great (356–323 BCE). At the
age of eighteen, Aristotle departed for Athens, where he
attended Plato’s Academy for twenty years. After Plato’s
death, Aristotle spent a couple of years in Asia Minor,
where he married and engaged in biological research.
When Alexander became king of Macedonia in 336 BCE,
Aristotle returned to Athens, where he established the
Lyceum, a rival school to Plato’s Academy. Plato’s
Academy continued until it was closed by Emperor
Justinian in the sixth century CE. After Alexander’s death
in 323 BCE, Aristotle came under suspicion as an agent of
Macedonia and was forced to flee Athens.

Aristotle’s works may be broadly classified into those
dealing with the theoretical sciences (e.g., physics, mathe-
matics, and metaphysics) and those dealing with the prac-
tical sciences (e.g., ethics, political science, rhetoric, and
poetics). Informing all of Aristotle’s works is his approach
to logic. The six logical works are the Categories, On
Interpretation, the Prior Analytics, the Posterior Analytics,
the Topics, and On Sophistical Refutations. These works are
traditionally collected together under the title of the
Organon. Important works in the theoretical sciences are
the Physics, On the Soul, and the Metaphysics. In the prac-
tical sciences, the Nichomachean Ethics, Politics, and
Poetics are particularly noteworthy. All of these works have
been influential, in varying degrees, in the development of
the modern social sciences. But Aristotle’s influence has
been particularly important in the development of politi-
Arms Control and Arms Race

Arms control is a form of international security cooperation, or “security regime,” aimed at limiting, through tacit or explicit agreement, the qualities, quantity, or use of weapons. The term arms control has been used loosely to denote many things in international politics involving the reduction or elimination of weapons or the tensions that lead to their use, and even as a euphemism for militarily enforced disarmament, like that imposed on Iraq by the United Nations in the 1990s. But such phenomena often do not reflect the conventional meaning of the term as it is used by arms control scholars and practitioners: a meaning that implies a cooperative relationship involving reciprocity and mutually agreed restraints.

The three most important goals of arms control are (1) to lower the likelihood of war; (2) to reduce its destructive effects; and (3) to curtail the price of preparing for it. The first aim can be met by encouraging military postures that enhance deterrence and defense and thus make aggression less attractive; by reducing the instabilities of arms racing that may lead to war (see below); and by taking steps that make military “accidents” or unauthorized uses of force less liable to happen or to lead to war if they do. As for the goal of limiting damage when wars do break out, arms control measures may forbid the production, deployment, or use of certain military technologies. Finally, cost-savings can be garnered through quantitative or qualitative arms limitation agreements. Such economies are an important policy consideration, for resources not sunk into certain types of weapons can be used to promote security in other ways, or put toward other welfare-enhancing activities.

Regardless of how it mixes or prioritizes these objectives, arms control has a few essential interrelated characteristics. First, it is a political relationship between actors: Unilateral arms control is an oxymoron. This does not preclude unilateral steps toward disarmament or demobilization that one state may take in order to elicit reciprocity from others and thus launch an arms control process: The determining factor is the conception of an end-state involving mutual reductions, limitations, or other restraints. Second, arms control involves strategic interdependence—the parties engaged in it are sensitive to each other’s postures and actions, and their decisions to agree and comply with arms control depend on their beliefs about each other’s willingness to do likewise. Third, it involves at least tacit if not explicit bargaining because the incentives to cooperate that infuse the relationship are always mixed with some degree of conflict and incentives to compete.

TYPES OF ARMS CONTROL

It is useful to distinguish between rivalry-specific and general arms control measures. In the rivalry-specific form, adversaries seek to manage their security competition through agreements that are tailored to the shape of their strategic relationship, in order to make a more stable or at least less costly military balance. By contrast, general arms control measures aspire to universality: With a broad ambit and generic guidelines, they are meant to exert desired effects over the multitude of strategic relationships in international politics.

The 1922 Washington Naval Treaty, for example, was rivalry specific. In it, the United States, Britain, and Japan agreed to reductions in battleship fleets according to specific ratios of strength between them, and to a ten-year hiatus on new construction, as well as limitations on battleship tonnage and armaments. The goal was to stabilize the existing balance of naval forces at lower levels, and to forestall an arms race among the three parties. Similarly, in 1972, at the peak of cold war détente, the United States and the Soviet Union pledged in the first Strategic Arms Limitation Talks agreement (SALT I) to limit the number of ballistic nuclear missile launchers to then-current levels, and to abide by major limitations on the deployment of strategic missile defense systems. Behind these arrangements were mutually held cooperative and competitive goals: to slow down the arms race and reduce worrisome instabilities and to maximize restraints on the other side while minimizing those on one’s own side.

As for general arms control measures, the most extensive early efforts were the conventions produced at the Hague Conferences of 1899 and 1907. Those widely endorsed conventions promulgated, among other things, prohibitions on the use of certain types of arms, such as “dum-dum” bullets, poisonous chemical weapons, or bombs dropped from balloons. In 1925, during the heyday of the League of Nations, the Geneva Protocol was added to the conventions, reinforcing the prohibition on the use of deadly gases. Later in the interwar period, participants in the World Disarmament Conference in Geneva (1932–1936) tried to enact a blanket prohibition on the use and development of “offensive” weapons, which were (and still are) thought to be conducive to war. The effort was ill fated for many reasons, but chief among them was the bane of many such qualitative exercises—the thorny and politicized issue of distinguishing between offensive and defensive weaponry. At the Geneva conference, for example, Britain, France, and the United States argued that aircraft carriers were essentially defensive; conversely, Germany, Italy, the Soviet Union, and Japan asserted that they were inherently offensive because they were useful for launching surprise attacks. In the era of the United Nations, similar attempts to foster far-reaching agreements have been carried forward by groups of states in the General Assembly; the current locus of these efforts is the sixty-six-member Geneva Conference on Disarmament (CD). Begun in 1979, the CD has been the forum for adoption of the 1992 Chemical Weapons Convention and the 1996 Comprehensive Test-Ban Treaty, and for negotiating various additions to the 1975 Biological Weapons Convention.

The most recent general effort was the tightly focused 1997 Ottawa “Landmines” Convention, which prohibits the use, stockpiling, production, and transfer of antipersonnel mines and mandates the destruction of existing stocks. As a general measure with aspirations to universality, the treaty has had mixed success. As of 2007, 155 member states had joined, while 37 had not, including 3 permanent members of the United Nations Security Council: the United States, Russia, and China. However, although the United States has not signed the treaty, it has funded and supported demining efforts worldwide. Thus, even though many important countries have not signed the convention, it has had a tangible humanitarian impact. Demining efforts catalyzed by the convention have resulted in the removal of hundreds of thousands of mines, saving a large number of lives worldwide.

General and rivalry-specific characteristics of arms control can overlap—for example, when a rivalry-specific formula is nested within a more general arms control agreement. The most important and contentious arms control agreement of the early twenty-first century—the Nuclear Nonproliferation Treaty (NPT)—is a good illustration of this. The NPT, which first came into force in 1970, has a nearly universal membership (by 2007, 188 of the 192 members of the United Nations were signatories). Its general aims are to reduce and eventually eliminate the role of nuclear weapons in international politics. Behind these sweeping generalities are a variety of undertakings that apply specifically to two different “classes” of signatories—the Nuclear Weapons States (NWS) and the Non-Nuclear Weapons States (NNWS). The NWS parties “legitimately” possess nuclear weapons, but must work to reduce them (eventually to zero), and must not share them with states that do not possess nuclear weapons. The NNWS cannot “legitimately” possess nuclear weapons, but in return for foregoing them, they are entitled to develop nuclear energy for peaceful purposes, and to international support for those efforts channeled through the International Atomic Energy Agency (IAEA). Thus, although the NPT is a nearly universal and general agreement, it is politically oriented toward managing a dangerous and difficult imbalance between the nuclear haves and have-nots. Similarly, the parties to the 1990 Conventional Forces in Europe (CFE) treaty were all members of either the NATO or Warsaw Pact alliances. Although a general aim of the treaty was to reduce conventional forces in
Europe, its organizing principle was military balance between the two blocs. There was thus a strong rivalry-specific core within the broader general agreement.

Yet another form of arms control is the supplier-cartel regime, in which participants who share a leading position on a given weapons technology agree to restrict its transfer to other parties outside the cartel. A formula of this sort is wired into the NPT in that the NWS agree not to transfer nuclear weapons to NNWS. But the purest example is the Missile Technology Control Regime (MCTR), which enjoins parties possessing advanced ballistic missile capabilities not to export the technology to other states. Begun in 1987 by the United States and six of its closest allies (Britain, Canada, France, West Germany, Italy, and Japan), the MCTR cartel grew to thirty-three members, including Russia, and also attracted the “unilateral” adherence of a number of other key players, most notably China and India.

**PROBLEMS AND CRITIQUES OF ARMS CONTROL**

The most important general critique of arms control is that if states become or threaten to become aggressive, arms control is rendered irrelevant and even pernicious: It encourages false hopes, wastes political energies on panaceas, and, worst of all, lowers defenses that need rather to be raised. By the same token, critics contend, arms control is most readily achieved and likely to work when it is least needed—that is, when international politics are placid or when foes concur that the weapons in question lack utility. In the 1991 Strategic Arms Reduction Treaty (START I), struck after the cold war evaporated with the end of the Warsaw Pact and the withdrawal of Soviet forces in Eastern Europe, Washington and Moscow achieved stunning success in agreeing to 30 to 40 percent cuts in the number of deployed strategic nuclear weapons: Such cuts had been impossible in the hostile and distrustful atmosphere of earlier decades. Once the political bases for enmity are removed, arms control can seem easy.

In circumstances of rivalry, in which trust and confidence-building is most needed, solutions to the verification problem (of measuring compliance with arms control agreements) can prove elusive. Insistence on highly intrusive forms of verification, moreover, can mask a basic unwillingness to reach agreement and negotiations can become a charade: Here the goal is not to find common ground but merely to avoid taking the blame for the failure to do so. Assuming a workable verification mechanism can be agreed on, there remains, as Fred Iklé famously observed, the enforcement problem—how to punish the cheaters that are caught. There is nothing about an arms control treaty that can make sanctions automatic: Although effective verification may make it harder for cheaters to covertly “break out” of agreements, the basic political problem of when, where, and how to counter their threatening military power remains, and will be decided by the parties that are both willing and able to do something about it. Thus, although it is a form of international cooperation, arms control does not transcend power politics.

There is one more note of caution: Effective arms control agreements that do produce mutual verifiable cuts will expose new gaps and asymmetries in the balance of forces among potential rivals, and, as a result, may encourage them to channel new investments into other—and potentially more destabilizing—weapons systems. This is most likely to occur when, despite major agreements, the embers of political competition continue to smolder. One of the important effects of the Washington Naval agreements was to facilitate the parties’ shift of focus and resources to competitive aircraft carrier development—with portentous consequences for the outbreak and conduct of World War II in the Pacific.

Proponents of arms control do not deny that these problems exist, but they point out that arms control is not always hostage to the vagaries of the political environment—it can shape that environment too. Arms control is more than just a means by which states press fixed national interests; it involves a political process that may permit them to learn more about each other, to deflate exaggerated images of “the enemy,” and to conceive of interests in more compatible ways. If it is folly to pursue arms control with irredeemably aggressive states, it is just as foolish not to pursue it when the situation is less clear-cut, for arms control itself may help not only to bring clarity but also to prevent potentially aggressive states from becoming aggressors.

**ARMS RACE: CONCEPT AND CONTROVERSIES**

An arms race occurs only when parties for whom war is a possibility engage in strategically interdependent increases in the quantity and/or quality of weapons: Their respective acquisitions and buildups are meant to match or overcome the strengths of the other side. The element of strategic interdependence is central to the identification of the arms race as a phenomenon of international politics, which requires states to rely ultimately on their own military forces for security, because the military forces of other states may threaten them and there is no world government to protect them. In such a milieu, where falling behind one’s competitors can potentially lead to the gravest consequences, arms racing can be seen as a normal, survival-enhancing behavior.
Nevertheless, arms races are often considered harmful because they lead states that are trying to outpace each other to devote more resources to military preparations than would otherwise be necessary for their security. Increased military buildup, in turn, means that fewer resources can be devoted to other, welfare-enhancing activities. When the competitive dynamic of arms racing comes to dominate other principles for controlling acquisitions, the buildup (and concomitant waste) can mount precipitously. For example, during the most dramatic upswing of the cold war nuclear arms race, as the Soviet arsenal grew and American planners became ever more ambitious in their target selection, the U.S. nuclear warhead stockpile climbed from approximately 1,000 in 1955, to 18,000 in 1960, to 32,000 by 1967. It was very hard to understand why a much smaller (and cheaper) arsenal of warheads would not have been sufficient to achieve the main strategic purposes: deterring a Soviet nuclear strike on the United States, or a conventional assault on Western Europe.

The worst fears about arms races, however, are not that they are wasteful but that they can cause wars by feeding conflict-spirals that do not just reflect enmities, but create and reinforce them. In this view, arming itself may become the stuff over which states fight. The conflict-spiral premise is what makes many figurative uses of the term arms race inapt. It has, for example, been used to describe the spike in steroid use among the “slugger-elite” of professional baseball, and also the steady pace of microchip developers. But few would argue that the greatest danger of steroid use in baseball is that the supersized sluggers will eventually fall on each other in sudden bat-wielding melees, or that the technology race among microchip producers will lead to a cataclysmic collapse of the high-tech economy.

Two objections to the conflict-spiral conception of arms racing are often raised. The first and most intuitive is that arms races do not cause hostility but are its consequence. They reflect the maneuvering of rivals consciously seeking a margin of advantage that will permit aggression or deter it, not some unfortunate misunderstanding—and that being the case, builds may prevent war, because they reinforce mutual caution. Second, even if an arms race between status-quo-oriented states does sometimes culminate in war, their decisions to fight are based on concrete stakes and complex political judgments that simply cannot be reduced to reciprocal fears caused by the arms race itself.

Nevertheless, there is an impressive amount of research on the connection between arms races and war, most of which has tended to focus on a few key questions: Given that some arms races culminate in wars, whereas others do not, are certain types more conducive to war than others? Do the dynamics of qualitative races (in which competitors seek innovative capabilities that will render their rival’s obsolete) differ from quantitative races (in which competitors seek a numerical advantage in relatively comparable weapons)? Samuel Huntington’s answer to these questions blended the two concerns by arguing that quantitative arms races are more dangerous than qualitative ones because, among other reasons, quantitative races require increasingly costly sacrifices that put pressure on states to seek a quick and violent escape from the competition. Others have suggested that arms races that generate large swings back and forth in relative strength (thus creating tempting opportunities for aggression by the temporary leader) are the most dangerous. Still others have made the intuitive point that arms races which give big advantages to states that favor the status quo are more likely to result in peace than those which give big advantages to states with aggressive intentions (although this ignores the possibility that a status-quo state may want to use its temporary margin of strength to defeat an aggressive adversary before it, in turn, becomes stronger).

During the cold war, these concerns were amplified by the fact that the arms race in question was nuclear. If it had led to war, it would truly have been a “race to oblivion.” The survival of human life—let alone civilization—following a major nuclear exchange between the cold war rivals would be questionable. Furthermore, it was clear that unless effective arms control measures were taken to interrupt the competitive dynamic, the superpowers’ nuclear race would metastasize, creeping into other rivalries throughout the international system. Even if arms racing increased the likelihood of war only by small margins, as the number of nuclear “racers” multiplied so too would the prospects for nuclear holocaust. Concerns such as these provided the impetus behind the rivalry-specific and general nuclear arms-control efforts discussed above, and while the politics of the NPT remain contentious, and a number of crucial nuclear-weapons states are not members (Israel, India, Pakistan, and North Korea), the NPT does appear to have helped stem the contagion of nuclear arms and arms races among states.

As the cold war recedes, and with it the chilling imagery of a nuclear-arms-race-spiral, the concept of an arms race remains useful. It has striking relevance to an important issue of international security today: the militarization of outer space. From the 1960s to the 1980s, the Soviet Union and the United States experimented with weapons designed to destroy earth-orbiting satellites, which have tremendous civilian and military utility. The feared arms race in such weapons did not then materialize, and the end of the cold war put the issue on ice. In 2007, however, China surprised the world by testing an antisatellite weapon, challenging the presumption of the
United States’ military preeminence in space. Thus, the prospect of a space arms race was resurrected, and the question of whether such a race could become so intense as to raise the probability of war was reopened—along with the question of whether arms control could serve to prevent war.

Still, in the early twenty-first century concerns over the arms-race-spiral as a potential cause of nuclear war seemed to decline relative to fears of another nuclear nightmare scenario—that of “loose nukes” getting into the hands of terrorists. This perceived and perhaps real shift in nuclear risk raises important questions about the future agenda of arms control concerning nuclear weapons and other weapons of mass destruction: Can the existing nonproliferation regimes—with some clever rewiring—furnish satisfactory solutions? Or must a new matrix of rivalry-specific, general, and supplier-cartel agreements be contrived to manage risky relationships between states and nonstate actors? And if the latter is necessary, will the supportive international political context on which arms control depends take shape and be maintained? For common danger does not make security cooperation inevitable. Without a countervailing common will, a construct entirely contingent on politics, the states that oppose this danger will make a rabble, not a regime.

ARMSTRONG, LOUIS

1932–

Elliot Aronson is a prominent American social psychologist. Born in Revere, Massachusetts, on January 9, 1932, his career has spanned nearly fifty years. He is renowned as a creative methodologist who conducts carefully crafted, highly impactful experiments to explore the causes and consequences of human social behavior. His style of experimentation builds on the legacy of Kurt Lewin (1890–1947) and Leon Festinger (1919–1989). Aronson’s textbook, The Social Animal (9th ed., 2003), is widely used and highly regarded for its pedagogical innovations. He is also known for his work as coeditor of two editions (1969, 1985) of the important Handbook of Social Psychology. He has been a highly successful mentor of doctoral students, including many who have made significant contributions to the field of social psychology during distinguished careers.

Aronson earned a bachelor’s degree in 1954 at Brandeis University, where he was mentored by Abraham Maslow (1908–1970). He then earned a master of arts degree at Wesleyan University in 1956, and completed the PhD program at Stanford University in 1959, where his mentor was Festinger, known for developing the theory of cognitive dissonance. Aronson subsequently held faculty positions at Harvard University, the University of Minnesota, the University of Texas at Austin, and the University of California at Santa Cruz, where he has been professor emeritus since 1994. Since 2001 he has also been distinguished visiting professor at Stanford University.

Beginning in 1959 and continuing through the mid-1960s, Aronson published a number of widely cited experiments that tested derivations from the theory of cognitive dissonance, providing support for dissonance-theory explanations of such phenomena as effort justification (evaluating an outcome more positively after a high degree of effort was required to attain it) and insufficient deterrence (devaluing a forgone pleasure when the threatened aversive consequence was minimal). Aronson proposed a useful modification to the theory of cognitive dissonance by asserting that the dissonant cognitions must be self-relevant, and that dissonance reduction will be directed at preserving one’s self image. In the 1990s he returned to this topic in experiments that show that making salient a discrepancy between the behavior that one advocates for others and one’s own behavior (hypocrisy)
induces dissonance that is reduced by adopting behavior more in accord with what one has advocated for others.

Aronson's contributions include his work on the effects of disconfirmed expectancies, and a substantial body of work on the antecedents of interpersonal attraction, notably the gain-loss hypothesis, predicting that changes in the level of esteem received from another would be a more important determinant of attraction to that person than the overall amount of esteem received. Aronson is also well known in the field of education for his work on the jigsaw classroom. He and his colleagues conducted field experiments demonstrating that creating interdependence within student teams working on a school assignment leads to reduced prejudice against minority students or other out-groups, while maintaining or enhancing academic achievement. This technique is widely used in classrooms at all levels of elementary, secondary, and post-secondary education.

Aronson has received many academic and scientific honors, including the American Psychological Association's Distinguished Teaching Award (1980), its Donald Campbell Award for Distinguished Research in Social Psychology (1980), and its Distinguished Scientific Contribution Award (1999). He was also elected to the American Academy of Arts and Sciences in 1992, and received the Distinguished Scientific Career Award from the Society of Experimental Social Psychology in 1994. He received a William James Fellow Award for 2006–2007 from the Association for Psychological Science.

ARROW, KENNETH J.
1921–

One of the most active, influential, and respected economists of the twentieth century, Kenneth J. Arrow was born in New York City in 1921 and remained in that city through his early adulthood. After receiving a bachelor of sciences degree in mathematics from the City College of New York in 1940, he obtained a master's degree in the same field from Columbia University in 1941. During his graduate training in mathematical statistics his teachers Harold Hotelling (born 1895) and Abraham Wald nudged him toward economics. After working at the Cowles Commission in Chicago and the RAND Corporation in Santa Monica, Arrow received a doctorate in economics from Columbia University in 1951. He started his career at Stanford University and returned to that institution after spending the years from 1968 through 1979 at Harvard University. It was during that period, in 1972, that Arrow shared the Nobel Memorial Prize with John R. Hicks "for pioneering contributions to general equilibrium theory and welfare theory." In welfare theory Arrow's impossibility theorem is a towering achievement, and in general equilibrium theory Arrow is one of the founding fathers, along with Gerard Debreu.

THEORIES

Three distinct schools can be identified in post–World War II (1939–1945) American neoclassical demand theory (Mirowski and Hands 1998): the Chicago School, the Cowles Commission (at the University of Chicago), and Paul A. Samuelson's Massachusetts Institute of Technology (MIT). All three offered different solutions to the problem of the relationship of the law of demand to utility maximization and the interdependence of income constraints and income effects.

Arrow's contributions concern the so-called Cowles approach. Arrow's impossibility theorem was developed in his doctoral dissertation and established that under certain assumptions about people's preferences between options it is always impossible to find a collective choice rule in which one option emerges as the most preferred. In other words, it is logically impossible to add up or otherwise combine the choices of individuals into an unambiguous social choice. This has major implications for welfare economics and theories of justice. Along with Debreu, Arrow gave the first rigorous proof of the existence of a market-clearing equilibrium given certain restrictive assumptions. He extended the analysis to incorporate uncertainty, evaluate stability, and assess efficiency. The restrictive conditions under which the existence of equilibriums could be established, the difficulties encountered in efforts to prove the stability and uniqueness of competitive equilibriums,
and the general perception of limited usefulness have caused a shift away from Arrow-Debreu general equilibrium theory toward game theory in microeconomics.

Areas in which Arrow's legacy is most persistent are growth theory and information economics. In growth theory his research on innovation and learning by doing has served as a major inspiration for endogenous growth theory. For instance, Arrow was the first to construct a theoretical model of learning by doing, which was followed by many empirical studies by others. Yet whereas Arrow had imposed the restriction that increasing only capital (or only labor) does not lead to increasing returns, endogenous growth theorists such as Paul Romer (b. 1955) have gone to great lengths to disqualify that restriction. In information economics Arrow's evaluations of problems caused by asymmetric information in markets endure in analyses of moral hazard, adverse selection, and so on. Arrow's asymmetric information insights are of further importance for analyzing specific topics such as discrimination and education. For instance, Arrow offered the best and most complete model of racial wage differentials that are not based on productivity by making the phenomenon compatible with competitive equilibrium theory, more specifically by developing a model that includes signaling and screening mechanisms under conditions of asymmetric information.

CRITICISMS

Arrow's insights have not gone without criticism. His impossibility theorem in particular has sparked a literature that has found other impossibilities as well as some possibility results. For example, if one weakens the requirement that the social choice rule must create a social preference ordering that satisfies transitivity and instead only requires acyclicity, there exist social choice rules that satisfy Arrow's requirements. In addition, Amartya Sen (1982) has suggested at least two other alternatives based on relaxation of transitivity and removal of the Pareto principle. This has enabled Sen to show the existence of voting mechanisms that comply with all of Arrow's criteria but supply only semitransitive results. In response to Arrow's model of racial discrimination, others have developed a long list of criticisms and countered that the phenomenon must be understood in terms of the dual labor market hypothesis or radical models that build on the work of multiple labor analysts yet have added twists of their own. In spite of or perhaps as a result of these critical responses, Arrow's legacy within the economics profession is as rich as his work.

ARROW-DEBREU MODEL

The Arrow-Debreu Model is named after the Nobel laureates Kenneth Arrow (b. 1921) and Gerard Debreu (1921–2004). It is a formalized Walrasian economic equilibrium system, and the existence of its competitive equilibrium was proven by Arrow and Debreu in their joint work in 1954. Solving the long-standing problem of proving the existence of equilibrium in a Walrasian system, the Arrow-Debreu Model has been the central piece of the general equilibrium theory of economics since the 1950s.
At around the same time, the economist Lionel McKenzie (b. 1919) proved the existence of a competitive equilibrium of a general equilibrium model using a similar set of techniques, so the Arrow-Debreu model is sometimes also referred to as the Arrow-Debreu-McKenzie model.

The Arrow-Debreu model specifies a competitive economy in which there are finite numbers of consumers, commodities (some being used as production inputs), and production units. Consumers have a set of well-defined preferences (continuous, nonsatiated, and convex), and each consumer holds an initial endowment of the commodities, with a positive quantity of at least one commodity. The technology that converts inputs into outputs is either nonincreasing returns to scale or constant returns to scale. In this economy, every producer maximizes profit and every consumer maximizes utility over their budget sets. The equilibrium of the economy is characterized by a set of prices at which the excess demand is zero for every commodity, and producers make zero profit. These market-clearing prices are reached through a tâtonnement process, in which “a fictitious price-setter” facilitates the price adjustment following a set of rules that resembles the way in which prices are reached in the real competitive economy.

Formulated in a purely mathematical form, the Arrow-Debreu model can be easily modified into spatial or intertemporal models with proper definition of the commodities based on the commodity’s location or time of delivery. When commodities are specified to be conditional on various states of the world, the Arrow-Debreu model can easily incorporate expectation and uncertainty into the analysis. Theoretical extensions and applications have been made to analyze financial and monetary markets and international trade, as well as other subjects. With a general equilibrium structure, the model is applicable in assessing the overall impact on resource allocation of policy changes in areas such as taxation, tariff, and price control.

The model has been subject to the criticism that many of the assumptions it makes do not fit the workings of the real economy. However, this criticism is not unique to the Arrow-Debreu model; it also applies to all general equilibrium models that are heavily dependent upon rigorous mathematical proofs. In the case of the Arrow-Debreu model, the assumption that each consumer has to have in the initial endowment at least a positive quantity of all commodities (strong survival assumption) or of at least one commodity (weak survival assumption) has drawn substantial criticism. The tâtonnement process, which requires that all purchases be made when the competitive equilibrium is reached, is also claimed to be incompatible with the workings of a real economy, where purchasing at non-market-clearing price is often observed.

ARROW IMPOSSIBILITY THEOREM

SEE Arrow Possibility Theorem.

ARROW POSSIBILITY THEOREM

The Arrow (im)possibility theorem can be viewed as a generalization of the Condorcet paradox. Assume that three girls, Ann, Beryl, and Cathy, wish to have dinner together in a restaurant. They have a choice of three restaurants: a Chinese (c), a French (f), and an Italian (i). Ann prefers the Chinese to the French and the French to the Italian. Beryl prefers the French to the Italian and the Italian to the Chinese (and the French to the Chinese); Cathy has different preferences and unanimously decide that they will choose the restaurant on the basis of majority rule: a restaurant x will be ranked before a restaurant y if at least two of them prefer x to y. But Ann prefers the Chinese to the French and the French to the Italian (and, of course, the Chinese to the Italian); Ann’s ranking is cfi (c is ranked first, f ranked second, and i ranked third). Beryl prefers the French to the Italian and the Italian to the Chinese (and the French to the Chinese); Beryl’s ranking is fic. Cathy prefers the Italian to the Chinese and the Chinese to the French (and the Italian to the French); Cathy’s ranking is ifc. Using majority rule, the Chinese is ranked before the French, the French is ranked before the Italian, and the Italian is ranked before the Chinese (cfic ...). A choice is impossible.

For Arrow’s theorem, one considers a set X of alternatives (social states, candidates to an election, etc.) and a set of individuals (in the case of an election, voters), the number of individuals being a positive integer. Individuals have preferences over alternatives. If the number of alternatives is a positive integer (i.e., if X is finite), they rank these alternatives from the most preferred to the least preferred with possible ties. For instance, with three alterna-
tives, one can have a first ranked, a second ranked, and a third ranked (six possibilities), or two alternatives ranked first and the third alternative ranked last (three possibilities), or an alternative ranked first and the other two ranked second (three possibilities), or the three alternatives tied. This makes thirteen possibilities (thirteen complete preorders or weak orderings as they are indifferently known in mathematics). The main question of social choice is to associate a social preference or a choice—an alternative in X or a subset of X—to the individual rankings (one ranking by individual). An Arrovian social welfare function is a rule that associates a social preference that is a weak ordering (i.e., a social ranking if X is finite) to the individual weak orderings (i.e., individual rankings if X is finite). Among these rules, one can consider the rule saying that the social weak ordering is the weak ordering of some specified individual, or the rule saying that the social weak ordering is fixed whatever are the individual weak orderings. To avoid these kinds of rules, Arrow imposes four conditions.

Condition U (Universality). This condition states that the individuals can have any weak ordering (there is no extra rationality condition where some weak orderings could be excluded due, for instance, to some homogeneity in the preferences of the individuals). Consequently, for three alternatives and three individuals, there are 13³ data of individual weak orderings and 13²¹⁹⁷ social welfare functions (10²⁰⁰⁰ is 1 followed by 2,000 zeros!).

Condition I (Independence). The social preference between two alternatives, say a and b, depends only on the individual preferences between a and b. For instance, the social preference between a and b, given five alternatives a, b, c, d, and e, other things being equal, will be the same whether some individual ranks the alternatives abcede or acdeb. Majority rule satisfies this property, but scoring rules where points are attributed to alternatives according to their ranks in the individual rankings and the social preference is based on the sums obtained do not. This excludes, in particular, the standard American and British voting rules and the famous Borda’s rule. (For Borda’s rule, if individuals rank k alternatives without ties, the alternative ranked first in an individual ranking gets k-1 points, the alternative ranked second gets k-2 points, and so forth, and the alternative ranked last gets no point. The social ranking is determined by the sum of points obtained by the alternatives, with the alternative socially ranked first being the alternative whose sum of points is the greatest. Ties are possible in the social ranking; to avoid ties, one can use some tie-breaking device. For instance, if alternatives are election candidates, their age may be used to break a tie.)

Condition P (Pareto Principle). If the individuals unanimously prefer any alternative, say a, to any other alternative, say b, then in the social preference a is preferred to b. This condition, given Condition U, excludes constant rules. In particular, rules that would be imposed by a moral or religious code are excluded.

A dictator is an individual who imposes the “strict” part of his preference, that is, of his weak ordering (he does not impose indifferences—ties): a is socially preferred to b whenever he prefers a to b.

Condition D (Nondictatorship). There is no dictator.

The Theorem can now be stated: If there are at least two individuals and at least three alternatives, there is no social welfare function satisfying Conditions U, I, P, and D. The enormous number of social welfare functions has been “reduced” to none.

A common but somewhat dishonest interpretation is that democracy is impossible or possible only in a two-party system. It is clear that, from a formal point of view, one can challenge Condition U. This is done by restricting individual weak orderings—for instance, the concept of single-peaked preferences introduced by Duncan Black (1958) just does this. One can also challenge Condition I. This has been done by Donald Saari (1995) in his studies on scoring rules.

Kenneth Arrow’s book and papers on this topic are among the most brilliant scientific works of the last century. They were crucial in the introduction of the use of modern logical and mathematical concepts in economics and other social sciences, and were at the origin of a new scientific domain, social choice theory, that is now flourishing at the frontier of economics, political science, mathematics, philosophy, psychology, and sociology.

BIBLIOGRAPHY

The term *Aryan* is derived from the Indic word *ārya* (noble). The ancient Hindu *Rig Veda* (variously dated 4000–1200 BCE) uses *ārya* as a self-designation of its authors. According to another Hindu text, the *Manu Smriti* (c. sixth century BCE), the inhabitants of the *ārya-varta* (the Hindu heartland) were setting the standards for *dharma*. In the *Bhagavad Gita* (c. second century BCE), the Hindu god Krishna tells the warrior Arjuna that it would be *an-ārya* not to fight a just war. In Buddhism, *ariya* has an ethical connotation: not born but high moral standards make one an ariya. Gautama Buddha (c. sixth century BCE) taught the *ariya saccāni*, or the “(four) noble truths.” Jains also use the word as an expression of moral excellence. The word *ārya* also occurs in the *Zend-Avesta*, the oldest scripture of the Zoroastrians, which states that Iran is the “ariya country.” In 1875 Swami Dayananda Saraswati (1824–1883) founded the *Ārya Samāj*, a Hindu reform movement aimed at restoring Vedic religion by eliminating all later accretions to sacred Hindu writings known as Purana and excluding all foreign influences.

“*Aryan*” entered European scholarly discourse in the mid-nineteenth century through philology as a generic name for Indo-European languages. A major international interdisciplinary enterprise appeared under the title “Indo-Aryan research.” The Sanskrit scholar F. Max Müller (1823–1900) cautioned other scholars not to load the linguistic term with racial overtones, as had already been done by some anthropologists of his time. Joseph Arthur Conte de Gobineau (1816–1882) maintained that within the “white race,” the “master race,” the blue-eyed, blond-haired, dolichocephalic Aryans constituted the highest variant. Various Scandinavia, Lithuania, the (dried-out) North Sea, northern Germany, southeastern Russia, the North Pole, and the (mythical) Atlantis were claimed as the cradle of the Aryans. For at least two thousand years, Europeans, relying on ancient Greco-Roman traditions and on the *Genesis* story of the peopling of the earth after the great flood, assumed that their ancestors had migrated westward from the East. By the nineteenth century, when it had become accepted that the earth and humankind were much older than six thousand years and the claim of European cultural superiority seemed to have been established, the direction of migration was reversed. The Aryan Invasion Theory (AIT) that arose in England in the second half of the nineteenth century specifically suggested that “Aryan” conquerors brought horses, iron, Sanskrit, and the Vedas to India around 1500 BCE.

By the early twentieth century, it had become impossible to find any scholarly agreement on either the identity or the origin of an Aryan race: now ideology took over. Widespread racism in Europe and North America led to the creation of “scientific” race theories that not only justified white-black segregation, but also supported an increasingly militant anti-Semitism. Houston Stewart Chamberlain’s (1855–1927) *The Foundations of the Nineteenth Century* (1899) inspired the Nazi ideologue Alfred Rosenberg (1893–1946) to claim in his 1930 book *Der Mythos des 20. Jahrhunderts* (The Myth of the Twentieth Century) that the preservation of the purity and dominance of the Aryan race was the main agenda of the twentieth century. Rosenberg also used the publications of the racist-nationalist Gustaf Kossinna (1858–1931) and Hans Reinert (1900–1990), who held the chair for “Prehistory and Early Germanic history” at the University of Berlin, to prove his thesis. The so-called Aryan race, or *Herren Rasse*, included besides the North Germans also the Scandinavians, the English, and the (Nordic) North Americans. Rosenberg’s *Mythos* offered “scientific” grounding to the *Arier Paragraphen* (legislation requiring pure Aryan ancestry) through which the Nazi government in early 1933 forced all German Jewish civil servants into retirement; it also provided theoretical support for the genocide later carried out on Jews, Gypsies (Roma), and other so-called inferior races.

For many years following the Holocaust, the term “Aryan” rarely appeared in scholarly literature. It resurfaced in the 1990s in a controversy about the Aryan Invasion Theory in connection with the early history of India. While archaeological, anthropological, and DNA research has proven the (AIT) all but untenable, some philologists, such as Michael Witzel, and some historians, such as Romila Thapar, defend it. Karl Marx (1818–1883) had also believed in it.

In a different context, but related to the older race ideologies, the “Aryan Nations” movement in the United States, founded in 1974 by Richard G. Butler (1918–2004), has revived the issue through its use of Nazi symbols and vocabulary to promote its white supremacist anti-Semitic agenda. The Aryan Nations movement openly advocates the aims and strategies of Adolf Hitler.
(1889–1945), and supporters strive to establish a worldwide “Fourth Reich” dominated by “Aryans.”

SEE Afrocentrism.

ASCH, SOLOMON
1907–1996
Solomon Elliott Asch was a Polish-born American psychologist noted for his dedication to psychology as a natural science, his talent for designing arresting experiments, and a humanism that embraced cultural knowledge and sensitivity. For Asch, behaviorists and Freudians were alike in their reductionism. Asch aimed instead to represent the breadth and depth of Homo sapiens in a Gestalt psychology that focused on context and relationships.

Asch was born in Warsaw in 1907 and moved to the United States as a teenager. At City College of New York he majored in both literature and science. While completing his graduate studies in psychology at Columbia University, he took an interest in anthropology and attended seminars with Ruth Benedict (1887–1948) and Franz Boas (1858–1942). In 1930 Asch married Florence Miller and took her with him on a summer fellowship to study Hopi children and their culture in Arizona. Although these experiences laid the foundation for Asch’s humanist interests, his graduate work was more conventional. Henry E. Garrett (1894–1973) supervised his Ph.D. research and, in the custom of the day, gave Asch his thesis problem: to find out whether all learning curves had the same form.

After completing his doctorate in 1932, Asch became a faculty member at Brooklyn College. Soon after taking up this position, he met Max Wertheimer (1880–1943), a Gestalt psychologist who became the major intellectual influence in Asch’s life. When Wertheimer died in 1943, Asch succeeded him as chairman of psychology at the New School for Social Research.

Asch moved to Swarthmore College in Pennsylvania in 1947 and spent twenty productive years there. At Swarthmore, Asch was in daily contact with two of the brightest stars of Gestalt psychology: Wolfgang Kohler (1887–1967) and Hans Wallach (1904–1998). It was in this environment that Asch developed his classic studies of social psychology: “Forming Impressions of Personality” (1946); “The Doctrine of Suggestion, Prestige, and Imitation in Social Psychology” (1948); and “Studies of Independence and Conformity: I. A Minority of One against a Unanimous Psychology” (1956). Each of the three investigations joins an elegantly simple method with a question of surprising depth, and each poses a striking conflict.

For personality impressions, the conflict is between positive and negative traits in descriptions of a single person. Perhaps the most important result is that students given inconsistent information (that a person is both cold and friendly) have no difficulty producing a unified impression (friendly manner, cold eyes). One can imagine a world in which students complain that they can do no more than repeat back the trait list—how can they say more? Creativity in integrating information about others is so natural that it takes an experiment to make us wonder at our capacity.

For prestige suggestion, the conflict is between evaluation of a quotation (“a little rebellion, now and then, is a good thing, and as necessary in the political world as storms are in the physical”) and evaluation of the source to which the quotation is attributed (Thomas Jefferson or Vladimir Lenin). Others had found that agreement with an argument was higher when the source held a higher status. These studies had concluded that humans are irrational in attending to the source associated with an argument. Asch showed that the perceived meaning of the quotation is different, depending on the source: Jefferson’s rebellion is reform; Lenin’s is blood in the street. The difference in agreement comes not from blind associations but from creative interpretation of the combination of statement and source information. (Asch’s irony was that the quotation came, in fact, from Jefferson, and, in context, Jefferson meant blood in the streets.)

For conformity research, the conflict is between social and sensory information, as a phony majority contradicts visual reality about the length of a line. In the standard situation, the real subject has to render a judgment after six “fellow students” give the same obviously wrong answer. These conformity test trials are interspersed among numerous trials in which all give the correct judgment. Overall, subjects remain independent on two-thirds of the
test trials, but three-quarters of subjects conform to the majority on at least one test trial. Many have understood this result as indicating human weakness in the face of social pressure. Asch emphasized instead that independence was twice as likely as conformity and noted that social life requires sensitivity to the opinions of others.

These experiments are revealing because, in all of them, conflicting inputs elicit the human capacity for creative integration of these inputs. During the decades in which psychology was dominated by stimulus-response psychology and behaviorism, Asch was an inspiration for those who could still see the complexity of human perception and the richness of human culture. Asch's 1952 textbook, *Social Psychology*, conveyed his experimental humanism to generations of undergraduate students and remains worth reading today.

**ASIATIC MODE OF PRODUCTION**

In twentieth-century Marxist politics and social sciences, the concept of the Asiatic mode of production was at the center of debates and controversies over how to apply the idea of *mode of production* to non-Western societies. Marxist theorists also turned to the Asiatic mode of production to argue for different revolutionary strategies in societies subject to colonial and imperialist domination.

The concept's status within Marx's own work is uncertain. The young Marx's references to Asian societies are influenced by a political tradition that, from Aristotle (384–322 BCE) to Charles Montesquieu (1689–1755) and Georg W. F. Hegel (1770–1831), saw the Asian continent as characterized by political despotism and socioeconomic stagnation. The initial theorization of modes of production in Marx's *German Ideology* (1845) makes no mention of an "Asian" mode. His *Misery of Philosophy* (1847), however, discusses India as a society where village-based production coexists with common land property. After 1850 Marx's view of Asia became more systematic, and he outlined a specific mode of production for the region. A series of articles he wrote in 1853 for the *New York Daily Tribune* dealt in detail with the Indian case, and to a lesser degree with China. The chapter on "precapitalistic economic formations" in the *Grundrisse* (1857–1858) inserted the Asiatic mode of production into a theory of stages of social development, where it followed "primitive communism." Marx tended to chronologically overlap the Asiatic mode of production with slavery and feudalism as two other, successive precapitalist societies where laborers are not separated from the means of production.

Marx's definition of the Asiatic mode of production included the absence of private ownership of land, autonomous village communities, and a despotic centralized state in charge of public works, especially irrigation. To finance public infrastructure, the state extracts, mainly through coercion and the control of the armed forces, an economic surplus produced by local communities in the form of tributes and collective work. Once surplus is extracted, village communities remain relatively independent within their "self-sustaining" economies.

After the first volume of *Capital* (1867), the Asiatic mode of production almost disappears from Marx's writings. Friedrich Engels's (1820–1895) analysis of precapitalist societies in *The Origins of Family, Private Property, and the State* (1884) did not mention it. In the early twentieth century, socialist reformists of the Second International took the concept as a metaphor for Asia's backwardness; they saw in colonialism a force of development and modernization. Fervent disputes on the Asiatic mode of production reemerged in the aftermath of the Russian Revolution (1917). Vladimir I. Lenin (1870–1924) had, in fact, stigmatized the "Asiatism" of czarist Russia. The Stalinist Third International (Comintern), however, rejected the Asiatic mode of production in 1921 when in colonial societies it chose to support alliances between the proletariat and nationalist bourgeoisie against imperialism and indigenous ruling classes. The Comintern defined the latter as "feudal," avoiding in this way the concept of the Asiatic mode of production, which was seen as too closely associated with political despotism and therefore liable to be used against the Stalinist regime itself.
The critical positions of Leon Trotsky (1879–1940) and Evgenij Varga (1879–1964) nonetheless alluded to the Asiatic mode of production in proposing anticolonial alliances of workers and peasants against both foreign imperialism and local bourgeoisies. The concept was finally expunged from orthodox Marxism after 1930, as Stalin codified a rigid, mechanical succession of modes of production. Conversely, in *Oriental Despotism* (1957) the former Marxist sinologist Karl Wittfogel (1896–1988) employed Marx's original formulation as a polemical indictment of the Soviet state, which he characterized as a manifestation of totalitarianism akin to Asia’s “hydraulic civilizations.”

The Asiatic mode of production resurfaced in Marxist historiography and anthropology during the 1960s in a context of intensified anticolonial and anti-imperialist resistance. Maurice Godelier and other contributors to the French journal *La pensée* (Thought) asserted that this mode of production remained central throughout the work of Marx and Engels. Jean Chesneaux did not limit the concept's validity to Asia, but extended it to a variety of traditional societies. At the same time, these authors argued for a dynamic perspective to depart from the Eurocentric bias of orthodox Marxism, which saw precapitalist non-Western societies as stagnant and undeveloped. The Asiatic mode of production has also been severely criticized in Marxist debates. Barry Hindess and Paul Hirst refused to define it as a mode of production because it presupposes the state rather than explaining it through the analysis of social relations. Maxime Rodinson considered the concept a blunt and simplified way to encase highly complex societies. Claude Meillassoux noted the concept's excessive generalization as it conflates diverse social formations that share a tributary extraction of surplus. The distinctiveness of African realities led Catherine Coquery-Vidrovitch to propose an “African,” kinship-based, mode of production-reproduction. Finally, post-colonial studies have rejected the Asiatic mode of production concept, following Edward Said’s *Orientalism* (1978), seeing it as a reflex of the cultural stereotypes that underpinned European imperial expansion.

**BIBLIOGRAPHY**

or even accent remained largely excluded from full assimilation into American society.

Much research has been conducted on the relationship between minority group size and racial prejudice and discrimination. Some scholars have suggested that a perceived “racialized” threat to the dominant group from a minority group, even if the threat is unfounded, leads to increased prejudice against the minority group (Quillian 1995; Burr, Galle, and Rossett 1991; Fossett and Kiecolt 1989; Blumer 1958; Blalock 1967).

The second factor involves socioeconomic status or class. Groups that have economic resources tend to assimilate into society more quickly than groups that have few or limited resources. Groups with large financial resources are able to have greater access to education, jobs, and even politics. In the United States, for example, Cubans have achieved a greater level of assimilation compared to Mexicans (Saenz 2004). Although skin color is a factor explaining the relatively higher success of assimilation for Cubans (they tend to have lighter skin tones compared to Mexicans), the fact that Cuban Americans tend to be better off economically allows them greater mobility and access to good jobs and better education.

Finally, a third factor has to do with the historical context of a society. A number of scholars have argued that prejudice against immigrant groups is higher during economic downturns than in times when the economy is prosperous (Becker 1971). During economic difficulties, there is a tendency for the majority group to blame minority groups for a perceived loss of jobs, economic insecurities, and threat of job competition, and the level of hostility toward racial and ethnic minorities tends to rise. In other words, there is an inverse relationship between a society’s economic prosperity and discrimination against minority groups.

Although all three factors provide plausible explanations for understanding why some groups are more likely than others to assimilate, more contemporary analysis of assimilation reveals that a complex intersectionality exists between race, class, and the economy. However, many scholars have argued pointedly that race and colorism continue to be the most salient reasons why many minority groups are still referred to as “hyphenated Americans” (e.g., African Americans or Mexican Americans) rather than simply “Americans” (Bonilla-Silva 2001).

EARLY ASSIMILATION THEORIES

Robert Erza Park (1864–1944), one of the first American sociologists and scholars to focus on ethnic relations, is considered a founding father of early assimilation theories, although his take on assimilation can be traced to the works of earlier social scientists, such as Herbert Spencer, Hermann Schneider, William Sumner, Franz Boas, and Ruth Benedict, among others. Indeed it was Herbert Spencer’s analysis and explanation of how larger societies capture and integrate other peripheral cultures and societies into their own, often forcing them to adapt to the larger and more powerful society’s normative climate and values, that enticed Park into thinking more about the role race and ethnicity played in the larger equation. Other influential scholars who helped to shape Park’s sociological imagination were John Dewey, George Simmel, and Booker T. Washington.

Before Park, racial implications of assimilation were minimally discussed at best, but there were models centered on cultural or national levels of assimilation. For example, Hermann Schneider in his two-volume book World Civilizations (1931) developed (albeit on a very macro-level) one of the earliest models of assimilation, though he never used that term. According to Schneider, as civilizations advance technologically, they grow larger and begin to incorporate other cultures in a three-stage process. At stage one it is through migration, invasion, or conquest that civilizations progress. At stage two, a period of miscegenation and amalgamation takes place in which the two cultures physically mix with one another. Finally, stage three begets a period of internal conflict in which class dynamics are restratified and there is a re-creation of new cultural symbols in the form of art, music, literature. Schneider never envisioned this process as a linear one but rather as a cycle that repeated itself every time a civilization progressed.

Park’s assimilation theory, widely referred to as the “race relations cycle,” was one of the first to incorporate the term assimilation into a model. Park suggested that immigrants are incorporated into a given society in four stages: contact, conflict, acculturation, and assimilation. His theory was that all immigrants face hostility and struggles initially, but gradually they are able to shed their ethnic identities and conform to the normative climate of the dominant group in society. Eventually, then, the group melts right in with the dominant group (i.e., A + B = A). At the time that Park was conceptualizing his cycle of race relations theory, a massive number of immigrants from European countries (e.g., Irish, Italians, Jews) were slowly being incorporated into the social, economic, and political spheres of the United States. However, it remained unclear whether African Americans and other non-European groups would be able to do the same. Park assumed that, given time, non-European groups would be able to assimilate into the dominant culture in the same manner that European groups were already doing.

Park’s theory was widely accepted (Duncan and Duncan 1955; Burgess 1928), but not everyone agreed with the simplicity of his model. For instance, Emory Bogardus developed his own model in which he proposed...
seven steps toward assimilation, including the native population's curiosity about immigrants, followed by an economic welcoming, then competition, legislative antagonism, fair play, quiescence, and finally partial second- and third-generation assimilation (Bogardus 1930). The last stage of Bogardus's model is worthy of attention because he never claimed that immigrants would be able to assimilate fully into the receiving society but rather that second and succeeding generations would be accepted partially yet still sometimes scrutinized depending on their country of origin (i.e., $A + B = A + b$). Here the little $b$ represents the partial acceptance of certain second- and third-generation immigrants and their cultures. This is different from the concept of cultural pluralism, or the “salad bowl theory,” which suggests that both cultures remain intact and get along with each other. Bogardus's model has some of the same problems as Park's in that he made too many assumptions, particularly in regard to the initial acceptance of immigrants as mostly favorable. Bogardus is better known for his social distance scale (the “Bogardus scale”) used to measure the preferred distance between two groups of people. Although Bogardus's model of assimilation has remained relatively unknown, especially in comparison to the works of other assimilation scholars of his time, his social distance scale has been widely adopted as a measurement tool for racial and ethnic attitudes and levels of intimacy between groups, and both of these factors have been used as indicators of assimilation.

Milton Gordon dramatically overhauled and expanded Park's theory in the 1960s with a more complex model of two main stages along a mostly linear path to assimilation: acculturation and social assimilation. Stage one, acculturation, deals with the initial contact and the conflicts experienced by immigrants coming into another society. Stage two, social assimilation, is the interaction and slow process of developing friends, social networks, and intermarriage within the dominant culture, eventually leading to total assimilation, which is broken down into seven substages: cultural (acculturation), structural (participating in education, church, etc.), marital (amalgamation), identificational (self-identifying and shedding of ethnic background), attitudinal changes (prejudice), behavioral changes (discrimination), and finally civic assimilation.

As minority groups went through these stages, Gordon theorized three possible assimilation outcomes: Anglo conformity, cultural pluralism, and the melting pot. Anglo conformity, which Gordon dealt with in Assimilation in American Life: The Role of Race, Religion, and National Origins (1964), refers to the idea that the assimilation of the minority group into the majority group (i.e., Anglos) results in a loss of the norms, values, language, and culture of the minority group (i.e., $A + B = A$). Outcome two, cultural pluralism (also referred to as the “salad bowl theory” or “multiculturalism”), refers to the idea that minority groups are able to assimilate into the dominant groups' social structures (e.g., schools) while continuing to maintain their own cultures, traditions, and languages (i.e., $A + B = A + B$). Finally, Gordon's notion of the melting pot theory refers to the idea that the culture of a society changes as elements of minority groups are taken and incorporated into the values, norms, and institutions of the dominant group (i.e., $A + B = C$).

ASSIMILATION'S ROLE IN SCHOLARSHIP

Assimilation theorists took a beating in the 1960s and 1970s from scholars who argued that many racial and ethnic groups remained unassimilated in the United States, even though in some cases they had been in the country for three generations (Glazer and Moynihan 1963; Novak 1972). However, starting in the middle to late 1980s and continuing in the early twenty-first century, research on assimilation has been picked up and expanded upon by a whole new group of scholars. Changing the notion of what it means to be assimilated into the dominant culture, scholars such as Lisa Neidert and Reynolds Farley (1985) argued that although they have not achieved assimilation as defined by Park in his race relations cycle model, newer immigrant groups in the United States have achieved some level of socioeconomic success. Edward Murguia (1975) has suggested that anti-Anglo-conformity practices, such as those initiated by the Chicano movement in the 1960s, could also have drastic consequences for Mexicans and other immigrants who were seen as troublemakers and discriminated against because of their culture and heritage. A groundbreaking article by Richard Alba and Victor Nee (1997) offered a staunch counterargument to scholars critical of the assimilation concept. Their basic argument was that it is unnecessary to abandon the concept of assimilation in favor of new terminology, especially considering that the assimilation model is still useful in studying contemporary immigration in the United States.

One the best known assimilation theories, introduced in the early 1990s by Alejandro Portes and Min Zhou (1993), was segmented assimilation. Segmented assimilation refers to the idea that there are multiple routes to assimilation and that these routes are not necessarily positive in their outcomes. Depending on their national origins, wealth, skin colors, phenotypes, accents, social networks, and opportunities, some groups may be able to assimilate more quickly or easily than other groups. Historically western European and other lighter-skinned immigrants have been more successful in assimilating into mainstream American society compared to their darker-
skinned counterparts. Mary Waters’s *Black Identities* (1999) rocked assimilation theorists still using methods derived from Park and Gordon by suggesting that there are some immigrants (e.g., English-speaking Caribbeans) who are doing better than native-born Americans. Other authors, such as Portes and Ruben Rumbaut (1996), suggested that some second- and third-generation immigrants, because they are losing their cultural identities, fare less well compared to their parents and grandparents, who are viewed, for example, as hard workers.

Although Park’s assimilation model has proven unsuccessful at predicting assimilation of groups such as African Americans or Mexican Americans, it remains debatable whether assimilation theories have outlived their usefulness in the social sciences. Nonetheless, for many immigration experts, such as Richard Alba and Reynolds Farley, assimilation models are still a good predictor of future outcomes, because many social scientists predict that the United States will one day have a “majority minority,” which will change the pattern of who gets assimilated into the system and who does not.

**ASSISTED DEATH**

*Assisted death* is an umbrella term for a death that requires an intentional act or omission on the part of a second person. There are five categories of assisted death.

Withholding of potentially life-sustaining treatment is the failure to start treatment that has the potential to sustain the life of a person (for example, not providing car-
Withdrawal of potentially life-sustaining treatment is the stopping of treatment that has the potential to sustain the life of a person (for example, removing a feeding tube from a person in a persistent vegetative state).

Potentially life-shortening symptom relief is pain- or suffering-control medication given in amounts that may but are not certain to shorten a person’s life (for example, ever-increasing levels of morphine necessary to control an individual’s pain from terminal cancer where the morphine is known to potentially depress respiration even to the point of causing death, but it is not known precisely how much is too much as the levels are slowly increased).

Assisted suicide is the act of intentionally killing oneself with the assistance (i.e., the provision of knowledge or means) of another (for example, a person is bedridden with ALS, also known as Lou Gehrig’s disease, and her sister brings her a lethal dose of a barbiturate ground up in a glass of orange juice, and the bedridden person drinks it through a straw).

Euthanasia is an act undertaken by one person with the motive of relieving another person’s suffering and the knowledge that the act will end the life of that person (for example, a person is bedridden with ALS and her physician gives her a lethal injection of potassium chloride).

CONTENTIOUS ISSUES
It has been widely accepted for some time that the withholding and withdrawal of potentially life-sustaining treatment are both legally and ethically acceptable. Indeed, courts, legislatures, and professional health-care bodies have recognized that patients have a right to refuse treatment and that free and informed refusals made by competent individuals (or substitute decision makers on behalf of individuals) should be respected. However, two areas of significant tension remain. First, there is debate about whether artificial hydration and nutrition are different from other forms of treatment (e.g., cardiopulmonary resuscitation) and therefore should be treated differently. Second, there is debate about whether health-care professionals have the authority to unilaterally withhold or withdraw potentially life-sustaining treatment—for example, where the family of a patient in a persistent vegetative state believes that ongoing treatment is what the patient would have wanted or is in the patient’s best interests, while the health-care team claims that the treatment would be “futile.” Can the health-care team proceed against the family’s wishes and stop treatment? This is a question that has not yet been settled in either law or in ethics.

It has also been widely accepted that the provision of potentially life-shortening symptom relief can be appropriate end-of-life care. However, there is still a great deal of uncertainty at the margins. That is, how much medication is too much? When does symptom relief shade into euthanasia? Are there limits on when such symptom relief is appropriate? For example, does a patient need to be terminally ill or could potentially life-shortening symptom relief be provided to someone with a chronic illness? There is also growing controversy over the practice of total or terminal sedation (sedation to the point of unconsciousness). The practice is controversial largely because it creates a physical dependence on artificial hydration and nutrition, which can then be withheld, leading to certain death.

Both assisted suicide and euthanasia are clearly illegal in the United States (with the notable exception of Oregon, which has legalized physician-assisted suicide). Many books and articles have been written about the legal and ethical arguments for and against decriminalization of euthanasia and assisted suicide. Opponents frequently emphasize beliefs about the sanctity of life, dignity, and slippery slopes. Proponents frequently emphasize beliefs about autonomy and dignity and reject slippery-slope arguments. A sharp divide can be found on the issue of whether there is a valid moral distinction between the withholding and withdrawal of potentially life-sustaining treatment, and the provision of potentially life-shortening symptom relief on the one hand and euthanasia and assisted suicide on the other. Public opinion is certainly split but, with consistency over a significant period of time, a strong majority of Americans support both euthanasia and assisted suicide.

ASSOCIATIONS, VOLUNTARY

Voluntary associations are associations that people voluntarily join. Voluntary associations may be religious, fraternal or sororal, economic, social, cultural, or political. There are three types of membership incentives: social solidarity (a term used by James Q. Wilson), purposive, and material (Wilson 1995). Social solidarity incentives include the satisfaction of getting to know other people and networking with others. Purposive incentives involve working with an association to fulfill a social, political, or economic interest in society. Material incentives provide members with some tangible benefit (e.g., a discount card).

Associations facilitate people’s participation in civil society. Such civic engagement makes for a more connected society. As people get to know one another by way of their civic associations, they can in turn use their relationships to help accomplish other goals or objectives. People thus gain capital socially, what is also referred to as social capital. Social capital is composed of those “features of social organization, such as trust, norms, and networks that can improve the efficiency of society by facilitating coordinated actions” (Putnam 1993, p. 167). As one’s social networks increase, one’s ability to organize and effect change in one’s interests is also increased (Putnam 1993, 2000). Increased interconnectedness is believed to increase social productivity. Yet social capital may be used for positive or negative circumstances. Positive uses of social capital contribute to a better society.

Those who participate in organizations face problems of collective action (Olson 1971). They have to overcome problems related to coordinating tasks among group members and problems related to limited resources. Limited resources can exist in the form of smaller memberships, limited financial resources, limited communication between members, and limited networks with other associations or institutions. Trust is a resource that can reduce some of the problems related to collective action. Those who are more trusting in others, who exhibit more social trust, can associate with others more freely and can later use these relationships to their benefit by asking for reciprocation.

While trust is an important resource in social relations, it is also important in the relationships between people and government, where it is referred to as political trust (Hetherington 1998, 2001, and 2005). When citizens trust in government, the relationship between citizens and government is more positive (Hetherington 1998). Political efficacy affects perceptions of trust in government: Those who feel that they have a say in government or who feel that they have some effect on changes in government tend to trust in government more (Brehm and Rahn 1997). Those who exhibit more social trust also trust in government more (Brehm 1998). Over time, social trust (Putnam 2000; Rahn and Transue 1998) and political trust (Putnam 2000; Hetherington 2005; Rahn and Transue 1998) have been declining in the United States. Since their heyday in the late nineteenth and early twentieth centuries, memberships in associations have also been declining (Gamm and Putnam 1999).

Distrust of people or government may have a deleterious effect on society. As social networks decrease, memberships in associations also decrease. Distrust leads citizens to feel less connected to government, but it also protects people against the possibility that their relationships with others or with government might be abused (Hardin 2004).

Collective action can also be important for countering government actions that disfavor people’s interests. People, however, also may face collective action problems when they try to coordinate large numbers of people to participate in activities to represent their interests. Despite the organization of associations, some people may be more likely to participate in associational activities than others. This leads to those who do not participate in associational activities free-riding on the work of those who do participate and still reaping the benefits of collective action (Olson 1965). The power of collective action, however, is also evident by way of social movements, when large numbers of people and sometimes several associations and their members can protest en masse for change. Moreover, social movements can connect the networks of many people and many associations to represent their interests more broadly (Tarrow 1994).

**ATHEISM**

Atheism, put simply, is the view that God does not exist. Cognitive atheism entails that, owing to the direction of the overall available evidence, people should believe that God does not exist. Doxastic atheism, in contrast, entails that one actually believes that God does not exist. A doxastic atheist can say: I believe that God does not exist, but I have no view regarding the status of the overall available evidence regarding God's existence. A person could thus be a doxastic atheist without being a cognitive atheist. Cognitive atheists about God, however, are logically required to recommend doxastic atheism about God, at least on cognitive grounds, even if they fail at times actually to believe that God does not exist. In the history of philosophy, Democritus (c. 460–c. 370 BCE), Epicurus (341–270 BCE), Ludwig Feuerbach (1804–1872), and Friedrich Nietzsche are widely regarded as supporters of atheism.

Theism is the denial of atheism. Cognitive theists hold that, owing to the overall available evidence, people should believe that God exists. Doxastic theists, in contrast, hold that God exists, even if they have no position on the overall available evidence regarding God. Cognitive theists must recommend doxastic theism about God, at least on cognitive grounds, even if they fail at times actually to believe that God exists. Another alternative to atheism is agnosticism, whose cognitive version entails that, owing to highly mixed overall evidence, people should withhold judgment (neither believe nor disbelieve) that God exists. Cognitive atheism entails that cognitive theism and agnosticism get the available evidence wrong. It implies that the evidence counts decisively against the existence of God.

If reality is just material bodies in motion, then atheism is true, since God would not be just a material body in motion. That would be a quick case for atheism, but a problem arises: decisive evidence for holding that reality is just material bodies in motion is lacking. At least this is a topic of ongoing controversy among philosophers.

Another case for atheism would be: If God exists, the evil found in this world would not exist; this world's evil does exist; so God does not exist. Here, again, the case would not be decisive. No decisive reason exists to think that God would not allow the evil found in this world. Certainly God could allow for various kinds of beings with free wills, and they could be causally responsible for much, if not all, of the evil in this world. A problem arises from the limited cognitive resources of human beings. People are simply not in a position to know that God would not allow the evil found in this world. God would be a moral tyrant in causing the evil in this world, but theism does not imply otherwise.

A big issue concerns whether cognitive atheism allows for due cognitive modesty for humans. Can one reasonably suppose that all available evidence has been canvassed in a way that calls for belief that God does not exist? This is a tall order, and it seems doubtful that one can plausibly answer yes. At any rate, God might seek to be elusive for various reasons, as recent work on divine hiddenness indicates. So atheism invites reasonable doubt about itself,
Attachment Theory

Attachment theory, formulated by British psychiatrist John Bowlby (1907–1990), focuses on the child-parent relationship and the influence of that relationship on subsequent child development (Bowlby 1969/1982, 1973, 1980). Since Bowlby's original writings were published, attachment theory and research have burgeoned, largely bearing out Bowlby's tenets about the importance of attachments to human development across the life span.

Bowlby’s Attachment Theory

According to attachment theory, the infant-parent attachment is an evolutionarily adaptive relationship whose principal function is the protection of the child. Bowlby argued that all people are genetically predisposed to form enduring and preferential relationships with principal caregivers because in the earliest environments of human beings such relationships were evolutionarily advantageous.

In addition to his concern with all people’s attachments, Bowlby focused on differences between individuals. At the heart of Bowlby’s thinking about individual differences is the notion of internal working models. Specifically, Bowlby argued that individuals draw on their earliest experiences to create mental maps, or internal working models, to guide their behavior. Internal working models guide people’s expectations, attention, interpretations, and memories. These processes then guide behavior.

According to attachment theory, it is the responses of parents to their infants’ earliest behaviors (crying, looking, reaching) that most heavily influence the development of the infants’ internal working models. Specifically, Bowlby asserted that repeated daily interactions between infant and parent lead the infant to develop expectations about the parent’s caregiving. These expectations are gradually organized into internal working models of the caregiver and of the self in relation to this caregiver. Sensitive, supportive caregiving leads to the development of an internal working model of the caregiver as trustworthy and helpful, and of the self as deserving of supportive care. Insensitive, unsupportive caregiving leads to working models of the caregiver as unavailable and untrustworthy, and of the self as unworthy of supportive care.

With continual use, internal working models come to operate automatically and unconsciously. Over time, individuals are more likely to define their experiences using existing working models than to modify their internal working models to accommodate new, possibly inconsistent information. In particular, people’s working models guide the development of subsequent relationships. This occurs initially by their guiding the individual’s expectations about others’ emotional availability: “the kinds of experiences a person has, especially during childhood, greatly affect . . . whether he expects later to find a secure personal base, or not” (Bowlby 1979, p. 104). Barring major changes in the environment or the individual, the principal qualities of the infant-parent attachment(s) will be replicated in subsequent close relationships: infants who received sensitive, supportive care will subsequently form supportive, nurturing, close relationships; infants who received insensitive, unsupportive care will form close relationships in which the giving and receiving of care is distorted.

It is important to note that internal working models are not considered to be immutable. As environments and individuals change and develop, working models are likely to require updating; major changes in the environment or in the person require the reformulation of internal working models. Factors such as traumas, losses, and new attachments are those most likely to alter internal working models.

Patterns of Attachment

American psychologist Mary Ainsworth (1913–1999) was a lifelong collaborator with Bowlby. Ainsworth’s development of the laboratory Strange Situation procedure galvanized the systematic study of individual differences in infant-parent attachment (Ainsworth et al. 1978). The Strange Situation is a twenty-minute videotaped assess-
Attachment Theory

ment with a twelve- to twenty-month-old infant, the infant's parent, and an unfamiliar female “stranger.” There are two brief infant-parent separations during which the infant remains in a laboratory playroom with a selection of toys. Based largely upon the infant's response to the parent during the two reunion episodes, the Strange Situation classification system distinguishes three main patterns of infant-parent attachment: secure, insecure-avoidant, and insecure-ambivalent.

Approximately 65 percent of infants in most non-pathological samples are classified as secure. During reunion, these infants actively seek to reestablish contact with their parent. Comforted by their parent's return, secure infants then return to play. In their inclination to seek and receive comfort from their parent and then resume exploration, secure infants are thought to use their parent as a “secure base from which to explore.”

Approximately 20 percent of infants in most non-pathological samples are classified as insecure-avoidant. Infants classified as avoidant are unlikely to cry during the separations. During reunion, these infants actively avoid interaction with the parent and may appear to ignore their parent completely. In their lack of comfort-seeking, avoidant infants appear less able than secure infants to rely on their parent as a secure base.

Approximately 15 percent of infants in most non-pathological samples are classified as insecure-ambivalent. Infants classified as insecure-ambivalent are highly likely to express distress during the separations. During reunion, however, these infants appear to derive little comfort from their parent's return. These infants demonstrate ambivalence about interacting with the parent that is frequently accompanied by angry, resistant behavior. In their inability to be soothed by their parent, ambivalent infants appear less able than secure infants to rely on their parent as a secure base.

Following Ainsworth's identification of these three patterns, Mary Main and Judith Solomon (1986) identified a fourth group: insecure-disorganized. Disorganized, disoriented, and frightened reunion behaviors characterize the infants in this group. When an infant is classified as disorganized, the infant is also assigned to the principal attachment pattern (secure, avoidant, or ambivalent) that most strongly coexists with or underlies the infant’s disorganization.

The four patterns of attachment are especially valuable for understanding human development because, as demonstrated by a large body of research, early patterns of attachment consistently forecast later development (Thompson 1999). In brief, children who are classified as secure during infancy later appear more socially competent than children who were classified as insecure. They have more positive interactions with friends and peers; they are also more empathic and less hostile, aggressive, or withdrawn. Infants classified as disorganized are considered most at risk for future emotional and social problems. In addition, consistent with Bowlby's earliest predictions, these four patterns are also consistently predicted by specific patterns of parenting behavior (Berlin and Cassidy 2000). The disorganized pattern is consistently associated with parental maltreatment (abuse or neglect).

Since the advent of the Strange Situation, numerous other assessments of individual differences in attachment have been developed: the Attachment Q-Sort is an adult-report measure of attachment in infants and young children (Waters et al. 1995). Using modified Strange Situation procedures, researchers have also developed systems for classifying attachment patterns in preschool children (Cassidy and Marvin 1992; Crittenden 1994) and in five- to seven-year-old children (Main and Cassidy 1988). (See Solomon and George [1999] for a discussion of these and other measures.)

After the Strange Situation, the second most widely used assessment of attachment is the Adult Attachment Interview (AAI) (George et al. 1985; Hesse 1999), a one-hour semistructured interview that assesses the adult's current “state of mind with respect to attachment” (i.e., the current internal working models). During the AAI, adults are asked to discuss early childhood experiences and their influences on adult personality. Although the AAI draws heavily on recollections of early attachment experiences, it is the ways in which the interviewee discusses these experiences that figure most importantly in the individual's classification into one of four patterns: secure, insecure/dismissing, insecure/preoccupied, or insecure/unresolved. Consistent with the theory, adults' patterns of attachment reliably predict: (1) the adults' parenting behaviors, and (2) the quality of their child's attachment to them. A second arm of adult attachment theory and research uses adults' self-reports about the way they usually feel and act in romantic relationships to assess “adult attachment style,” both in terms of romantic attachments and more generally (Bartholomew and Horowitz 1991; Hazan and Shaver 1987; Rholes and Simpson 2004).

CLINICAL APPLICATIONS

Since the late 1980s, interventions based on attachment theory and research have proliferated in various settings across the United States and abroad. The field of attachment-based interventions has only just begun to gain order and systemization, especially with respect to the use of theory- and research-based protocol (Berlin et al. 2005). Attachment theory and research are also beginning to be integrated into the diagnosis and treatment of children with reactive attachment disorder, a set of seriously
aberrant and problematic attachment behaviors typically associated with parental maltreatment or disruptions in early caregiving relationships. Theory- and research-based interventions to enhance early attachments among high- and low-risk parents and children are a promising avenue toward supporting human development on the whole.

ATTENTION-DEFICIT/HYPERACTIVITY DISORDER

Attention-deficit/hyperactivity disorder (ADHD) is a diagnostic label describing children and adults who demonstrate developmentally inappropriate levels of inattention, hyperactivity, and impulsivity. This disorder has been identified by many different names in the past, including attention-deficit disorder (ADD) with and without hyperactivity. It is one of the most commonly diagnosed disorders of childhood and accounts for a significant percentage of referrals to mental health and primary care clinics. Once considered a childhood disorder that one would “grow out of,” it is now recognized that symptoms and impairment persist across the lifespan for many individuals, with an increasing number of adults seeking treatment. Although prevalence rates vary as a function of diagnostic method, it is estimated that 5 to 8 percent of children and 1 to 3 percent of adults meet criteria for ADHD as outlined by the American Psychiatric Association (1994). ADHD is more often diagnosed in boys, but prevalence rates are fairly consistent across diverse geographic and racial populations.

DIAGNOSIS

The Diagnostic and Statistical Manual of Mental Disorders (DSM-IV), the primary reference for mental health professionals in the United States (APA 1994), identifies three subtypes of ADHD: predominantly inattentive, predominantly hyperactive-impulsive, and combined. At
least six of nine inattentive or hyperactive-impulsive symptoms must be present for at least six months for diagnosis, with the subtype determined by which symptoms are predominant. Inattentive symptoms include inattention to details or making careless mistakes, difficulty sustaining attention, not listening, not following through and completing tasks, avoiding or disliking tasks requiring sustained mental effort, disorganization, forgetfulness, losing things, and distractibility. Hyperactive symptoms include fidgeting, difficulty remaining seated, being "on the go," running or climbing excessively (feelings of restlessness in adults), difficulty playing quietly, and talking excessively. Impulsive symptoms include blurtting out, difficulty waiting, and interrupting or intruding on others. These symptoms must be sufficiently maladaptive and developmentally inappropriate to warrant diagnosis.

**DSM-IV criteria** also require that at least some of the symptoms must have caused impairment for the individual before the age of seven. Although symptoms may be overlooked in some children when they are younger, particularly those who are higher functioning, the developmental nature of the disorder requires a chronic and pervasive pattern of difficulties across time. Thus, one cannot develop "adult onset" ADHD. When symptoms present in adulthood for the first time, there is often an alternative explanation for them, such as anxiety, depression, or another medical condition. Because inattention and hyperactivity-impulsivity can have numerous causes, diagnosis actually requires that symptoms are not better accounted for by another psychiatric disorder and that they do not occur solely in the context of a pervasive developmental disorder, schizophrenia, or other psychotic disorder. Finally, ADHD-related impairments must occur across settings (i.e., in the home, during social activities, and at school or work) and there must be evidence of clinically significant impairment in social, academic, or occupational functioning. That is, the symptom severity is more than mild and interferes in individuals' daily lives and activities. Although these criteria have limitations, notably their appropriateness for different ages and subtypes, they are the most rigorous and empirically derived in the history of ADHD.

When the DSM-IV criteria are carefully followed using well-defined practice parameters for children (AACAP 1997; AAP 2000), ADHD can be reliably diagnosed. The parent interview lies at the core of the assessment process and covers questions regarding symptoms, impairment, history (medical, developmental, psychiatric, and family), and alternative explanations for the child's behavior. Developmental history forms, symptom screening checklists, and diagnostic interviews are useful tools in collecting this information. Standardized parent and teacher rating scales that include ADHD-specific items aid in documenting developmental deviance and perverseness of symptoms. Additional feedback from the child's school, including testing reports and observations, may also be obtained. Although medical and cognitive tests are not routinely indicated, they may help identify coexisting conditions. Assessment of ADHD in adults includes the same basic components, with age-appropriate interviewing tools and the use of rating scales completed by the adult and another informant, such as a spouse or coworker (Weiss and Murray 2003). The reliability and validity of these measures are less well established, however.

Despite concerns about large-scale overdiagnosis, epidemiological studies have found little evidence of this. According to the 2003 National Survey of Children's Health that assessed over 100,000 U.S. children through parent phone interviews, approximately 7.8 percent of 4–17 year olds were reported to have been identified by a professional as having ADHD (Centers for Disease Control 2005). Similarly, William J. Barbaresi, Slavica K. Katusic, Robert C. Colligan, et al. (2002) found that 7.5 percent of children in a birth cohort of over 5,000 in Minnesota had received clinical diagnoses of ADHD according to medical record documentation. These numbers closely resemble prevalence rates found in carefully conducted diagnostic studies (Barkley 2006), suggesting that there is not substantial over-identification in practice. The American Medical Association came to a similar conclusion after reviewing over 20 years of literature using a National Library of Medicine database (Goldman et al. 1998). Rather, more children, particularly girls and adolescents, are being identified than in the past, particularly with recently changed and expanded diagnostic criteria. Nonetheless, some practitioners who do not conduct thorough evaluations using validated diagnostic criteria may be inappropriately diagnosing and treating children. Dramatically increasing prescription rates for medications to treat ADHD are also believed to represent more effective treatment patterns, although concerns of misuse and diversion are recognized.

**COURSE, IMPACT, AND COMORBIDITY**

Children with ADHD experience frequent learning difficulties and are more likely than others to be placed in special education, retained, and suspended; they are also more likely to fail to graduate. Furthermore, they are at higher risk for peer rejection, physical injury, delinquency, and substance use (Barkley 2006). Adults with ADHD are also at higher risk for smoking, drug abuse, driving citations and accidents, and poorer physical and mental health. They often experience higher levels of anxiety and depression, more job-related turmoil, and relationship difficulties (Wender 1995).
Outcomes for children with ADHD vary based on risk factors and the presence of coexisting psychiatric conditions, which commonly include oppositional behavior and conduct problems, anxiety, depression, tic disorders, and learning disorders. Overall, 15 to 20 percent of children with ADHD appear normalized as adults; 20 to 30 percent experience marked impairments in occupational, relational, and mental health functioning, and the remainder exhibit persistent symptoms with mild to moderate difficulties (Biederman et al. 1998). Factors predicting a worse outcome include psychosocial adversity, a family history of ADHD, and the presence of oppositional behavior (Biederman et al. 1996).

HISTORY OF THE DISORDER AND ITS TREATMENT

First described in the early 1900s, thousands of studies on ADHD were conducted in the latter half of the twentieth century, making this the most well-researched childhood disorder. Significant advances have been made in our understanding of the nature of ADHD, resulting in changes to diagnostic criteria and ongoing exploration of risk factors and prognosis. Once attributed to brain injuries or environmental maladjustment, the neurobiological nature of the disorder is now well established (Barkley 2006). Research suggests that the causes of ADHD are complex, although most cases can be accounted for by heredity. Neuroimaging research has identified frontal lobe functioning deficits and structural brain abnormalities associated with ADHD, and molecular genetics studies are investigating specific genes that may be implicated, with a goal of developing more sophisticated treatment strategies (Biederman 2005).

A wide range of treatments for ADHD has been developed, with many having little or no empirical basis (e.g., dietary interventions, biofeedback, and optometric training). Proven treatments for ADHD include parent-management training, direct behavior modification in schools and specialty camps, and stimulant medications, primarily methylphenidate products (AACAP 1997; Pelham et al. 1998). More recently, efficacy has been demonstrated for specific norepinephrine reuptake inhibitors such as atomoxetine. A multimodal treatment approach is generally considered the best practice, although knowledge of long-term benefits and methods for individualizing treatments is limited. There is also a lack of information on the availability and effectiveness of typical community and school services for ADHD. Use of stimulant medications remains controversial, although there is considerable evidence of short-term benefit for core symptoms in children (MTA Cooperative Group 1999) and growing support for the use of these medications in adults. Psychosocial treatments for adults that incorporate behavioral compensation skills and cognitive-behavioral modification are being developed but have not yet been well evaluated.

ATTITUDES

Attitude, one of the key concepts of social psychology, refers to people’s evaluations of entities in their world. Formally defined, attitude is a psychological tendency that is expressed by evaluating a particular entity with some degree of favor or disfavor. An individual’s evaluation is directed to some entity or thing that is its object—such as a person (Oprah Winfrey), a city (Chicago), or a theory (Darwinian evolution). The entity that is evaluated, known as an attitude object, can be anything that is discriminable or held in mind, sometimes below the level of conscious awareness.

Attitudes are initially formed when an individual’s first reaction to an exemplar of an attitude object leaves a mental residue that predisposes the individual to respond with the same degree of evaluation on subsequent encounters with the attitude object. This mental residue is a tendency to respond with some degree of positivity or negativity to an attitude object. Once an attitude is formed, it is expressed through the cognitive, affective, and behavioral responses that the attitude object elicits. The cognitive aspect of attitudes consists of associations that people establish between an attitude object and various attributes that they ascribe to it. The affective aspect of attitudes consists of feelings and emotions and physiological responses that accompany affective experience. The behavioral aspect of attitudinal responding refers to overt actions toward the attitude object as well as to intentions to act. These cognitions, affects, and behaviors all express positive or negative evaluations of attitude objects.

As people form attitudes based on cognitive, affective, or behavioral responding to an attitude object, they form associations between the attitude object and these responses. As evaluative meaning is abstracted from these associations, an overall abstract attitude may be derived from these more elementary associations. Yet attitudes do not necessarily take the form of simple, unitary evaluations. To represent attitudes’ complexity, psychologists have assumed that the mental associations underlying attitudes can have structural properties. For example, mental associations may be more or less ambivalent, or evaluatively inconsistent with one another. In addition many important structural properties derive from attitudes’ links to other attitudes—for example, attitudes may form ideologies when they are linked by a common theme, such as liberalisms or conservatisms.

Attitudes may be implicit or explicit. Explicit attitudes are evaluations that are consciously experienced and may be reported by the person who holds the attitude. In contrast, implicit attitudes are those that people do not consciously recognize. These implicit attitudes may be automatically activated by the attitude object or cues associated with it. Regardless of whether attitudes are explicit or implicit, they are a source of motivational and cognitive bias and therefore generally foster attitude-consistent beliefs, affects, and behaviors.

Attitudes are usually assessed through questionnaire techniques that elicit respondents’ endorsement of statements or other stimuli (called items) that imply positive or negative evaluation of an attitude object. Researchers typically combine each respondent’s reactions to these items according to a mathematical model that scales the reactions along an evaluative continuum that extends from very negative to very positive. Implicit measures of attitudes seek to assess attitudes without asking respondents for direct verbal reports of these attitudes. Such techniques may disguise attitude measures as tests of knowledge, assess physiological responses, or monitor the speed with which respondents associate an attitude object with positive or negative stimuli.

ATTITUDE CHANGE

Attitudes can be changed on the basis of cognitive, affective, and behavioral processes. Most research on change has concerned persuasion by informational messages. Classically the independent variables studied by persuasion researchers are categorized as source, message, channel (or medium), recipient, and context variables. Variables within a single category do not necessarily affect persuasion similarly, nor do they necessarily act on attitudes through similar processes or through similar processes in varying circumstances. The reasons for this empirical complexity lie in the multiple psychological processes that can mediate attitude change.

Persuasion theory, which has a long history in social psychology, examines psychological processes that serve as mediators of the effects of information on attitudes. Some of these theories have emphasized what can be termed systematic processing, that is, the detailed processing of a communication’s content that produces acceptance of its conclusions. Yet dual-process models of persuasion emphasize that, in addition to careful, systematic scrutiny of the content of messages, people may use simple decision rules or cognitive heuristics to assess the validity of
messages. For example, the decision rule that “experts' statements can be trusted” might underlie persuasion by an individual expert communicator. A key assumption of dual-process theories is that people process information superficially and minimally unless they are motivated to turn to more effortful, systematic forms of processing. Furthermore systematic processing can only take place if they have the capacity or ability to evaluate the argumentation contained in messages. Therefore persuasion theory's predictions about the effects of variables such as the characteristics of message sources are contingent on the ability and motivation of members of the target audience.

Another technique for changing attitudes is to induce people to engage in behavior that has implications for their attitudes. This research has featured competing theoretical positions that make differing assumptions about the psychological processes that produce such change. The best-known theory, cognitive dissonance theory, took the view that the behavior of advocating a position inconsistent with one's attitude creates cognitive dissonance, an unpleasant state of arousal that motivates attitude change. Behavior inconsistent with an attitude changes this attitude toward the behavior, but only when the incentive for the behavior is not seen as the main reason for the behavior. Dissonance is particularly motivating when an individual accepts personal responsibility for his or her behavior bringing about an unwanted consequence. An example of such an unwanted consequence is provided by the case of a speaker who persuades audience members to adopt a viewpoint that he or she does not privately endorse. If the inducement for this behavior is small and personal responsibility is present, the speaker would be likely to show attitude change toward the position advocated. This attitude change occurs because such behavioral acts threaten the speaker's self-identity or integrity unless attitude change makes the advocacy seem more consistent with his or her attitudes.

THE EFFECTS OF ATTITUDES ON BEHAVIORS

One of the greatest successes of attitude research is the substantial progress made in predicting behavior from attitudes. Relatively good prediction can be readily achieved if researchers design their measures of attitudes and behaviors appropriately. However, debates have ensued concerning the psychological processes by which attitudes influence behaviors. Many theories have assumed that people take the utility of behaviors into account in a rational cost-benefit calculation that determines behavior. However, other theorists have emphasized automatic links between attitudes and behaviors as well as the more deliberative route involving analysis of the utility of behaviors. According to the automaticity approach, attitudes can be formed automatically and then cause behavior to follow without any conscious reasoning process. Increasing the plausibility of relatively automatic attitude-behavior links is research suggesting that implicit measures of attitudes—but not explicit measures—can predict a variety of relatively spontaneous and subtle behaviors, such as nonverbal behaviors, that are for the most part not consciously controlled.

SCOPE OF ATTITUDE THEORY AND RESEARCH

In summary, many specific research topics are encompassed within the broad area of attitudes, which in general pertains to the evaluative aspects of human experience. Researchers are concerned with the causes of attitudes and their effects. A wide range of causes can form and change attitudes. The attitude itself can have various structural properties and may be implicit or explicit. Attitudes in turn influence cognition, affect, and behavior.

ATTITUDES, BEHAVIORAL

Attitudes are judgments people have about ideas, experiences, and other people. They can be conscious (explicit) or unconscious (implicit) beliefs that may influence behavior and decisions. Behavioral attitudes are attitudes that develop as a direct result of certain behaviors. However, because one may hold a negative attitude toward a specific behavior yet still engage in that behavior,
a person’s behavior does not always reflect his or her attitudes.

Social research on nonconformity at the group and societal level has yielded insights into attitude formation and behavior. An early and influential work was Oscar Lewis’s La Vida: A Puerto Rican Family in the Culture of Poverty, San Juan, and New York (1966). Lewis intended to show that the behavior of poor people—his book’s subjects—revealed key insights into how poverty itself generated a way of life that Lewis described as a distinct “culture of poverty.” Lewis’s work set off a highly politicized controversy in social scientific and policy circles over the causes of poverty and the complex issue of which social groups set and define the “norms” used to judge behavior as favorable or unfavorable. According to Lewis, poverty’s enduring nature cannot be attributed to structural constraints only, but also to poor peoples’ own attitudes and beliefs that prevent them from succeeding according to mainstream standards.

Research on unfavorable behavior has revealed the key role that norms play in all attitude formation, whether these norms are sanctioned at the group level, the societal level, or both (see for example Erikson 1966; Becker 1991). Many social scientists emphasize the way in which shared or socially held beliefs and attitudes—“norms”—link the individual to society (Tesser and Shaffer 1990). In contrast to a singular or independently developed attitude, belief systems are larger structures that link individual attitudes together. Human behavior is thus continuously mediated between socially situated attitudes (norms) and an individual’s attitudes. Jary and Jary (1991), integrating various definitions, argue that attitudes contain three elements: the cognitive, the affective, and the behavioral. Using the framework of behavioral action and attitudes, social scientists have focused their empirical research on the societal and group context in which attitudes and beliefs, and their attendant actions, occur. Some social scientists differ over the weight to ascribe to the individual, group, or society in attitude formation, but generally their numerous studies of behaviors—both conforming and deviant—have revealed the complex nature of the interactions between the various levels at which attitudes are formed, beliefs are generated, and behaviors are enacted. The behavioral attitudes exhibited by Lewis’s subjects, for example, may not have been a reflection of their individual-level “positive regard” for the behaviors so much as the group-level “coping strategy” for dealing with the results of generations of poverty.

ATTITUDES, POLITICAL

Political attitudes can be broadly defined as the opinions and values individuals hold about political issues, events, and personalities. Social scientists first began the systematic study of these attitudes in the 1930s and 1940s. Surveys had been used sporadically prior to this time, but it was not until the publication of The Peoples Choice in 1944 that scholars began to examine the impact of media exposure and campaign-related events on evaluations of the major party presidential candidates. This study by Paul Lazarsfeld, Bernard Berelson, and Helen Gaudet of the 1940 U.S. presidential election focused on a single community in Ohio and found that political messages conveyed through the mass media were not especially persuasive. That is, instead of media messages influencing voters to support a candidate they might otherwise have opposed, it simply reinforced existing predispositions.

Other studies followed with essentially the same conclusion. Messages conveyed through the mass media could be effective in passing along information, but not in changing opinions. Subsequent research modified this finding somewhat by uncovering a variety of indirect effects from media exposure. It turns out that, although the media cannot effectively tell individuals what to think, it can often influence them as to what to think about. This effect, known as agenda setting, stipulates that when the mass media focus on a particular topic—for example, defense spending—those exposed to the message are more likely to think this issue is an important one for the country. Similarly, when the media highlight a particular issue or set of issues, these matters become more important in the evaluation of political candidates. For example, a variety of experimental and survey-based studies have found that emphasizing racial considerations in the media results in attitudes about race being more heavily correlated with
attitudes about crime, welfare, or candidate preferences. In short, the mass media tend to have greater indirect effects rather than direct effects on public opinion.

GROUP DIFFERENCES IN PUBLIC OPINION
One common theme in the study of public opinion is the examination of various social group differences in political attitudes. Scholars have typically focused on age, gender, class, and racial group differences. Often, attitudinal differences across these demographic groups are relatively small and inconsistent. For example, the elderly and the nonelderly rarely differ on matters of public policy. The elderly are more attentive to perceived threats to programs such as Social Security or Medicare, but the overall levels of support are virtually indistinguishable. Gender differences in public opinion are also less pronounced than some might think. On a wide variety of issues, the views of men and women are remarkably similar. There are some exceptions, however. In terms of partisanship and ideology, women are somewhat more likely than men to identify as Democrats and liberals. Similarly, since at least 1980, women have been somewhat more likely than men to support Democratic presidential candidates. The differences usually range from ten to fifteen percentage points. In the area of policy preferences, the most prominent gender differences are with issues concerning violence and the use of force. Women tend to be less supportive of these issues (e.g., war, capital punishment, permissive gun control, etc.) than men. Women are also more supportive of gay rights and slightly more liberal on social welfare spending, some measures of racial attitudes, and environmental issues. Interestingly, men and women do not differ dramatically in their levels of support or opposition to abortion, although women do tend to regard the issue as more important than men.

The effects of social class on political attitudes are also uneven. On balance, voters in the bottom half of the income distribution tend to vote for Democratic presidential candidates but this association is not strong and it has been declining over time. In terms of public opinion, studies show that citizens with lower incomes are more likely to support social welfare programs. These differences are usually on the order of ten to fifteen percentage points. Less affluent citizens are not, however, more likely to favor a progressive income tax or other taxes that disproportionately affect the wealthy. On most noneconomic issues there are virtually no class differences.

Racial differences in public opinion represent, by far, the largest demographic divide in political attitudes. This is especially true in the case of the views of whites and African Americans. On a range of racially tinged issues, such as efforts to end employment discrimination, support for school desegregation, and affirmative action in the workplace and in higher education, blacks and whites have differed by as much as fifty percentage points. Racial differences also emerge, of only slightly smaller magnitudes, on ostensibly nonracial issues, such as funding for welfare, food stamps, education, and Medicare. Donald R. Kinder and Nicholas Winter explored these differences in a 2001 article and tried to isolate the causes. Their results differ depending on whether the issue domain involves race-based policies or social welfare issues. In the case of the former, the racial divide is primarily explained by differences between African Americans and whites in political principles (e.g., egalitarianism and limited government), as well as in-group identification and out-group resentment. Class differences do not play a significant role. In the case of social welfare attitudes, the racial divide is mostly driven by all of the previous factors listed along with, to a lesser extent, social class differences between blacks and whites.

One final feature of public opinion with respect to groups is worth mentioning. Since the early part of the twentieth century, there has been a dramatic change over time in attitudes about disadvantaged groups in society. This is perhaps best illustrated in the case of attitudes about women’s rights and tolerance toward African Americans. In both cases, these changes are due, at least in part, to the conscious efforts of social movements to change public opinion. For example, Howard Schuman and his colleagues (1997) report that in 1942, 68 percent of whites in a nationally representative sample endorsed the idea that black students should go to separate schools from whites. By 1995, however, this figure had declined to a mere 4 percent. Similarly, in the case of attitudes about gender roles, Virginia Sapiro notes that in the early 1970s roughly one-third of Americans agreed that women should “take care of running the homes and leave running the country up to men” (2002, p. 35). By 1998, only about 15 percent of respondents adopted this position.

Schuman, Howard, Charlotte Steeh, Lawrence Bobo, and Maria Krysan. 1997. Racial Attitudes in America: Trends and
ATTITUDES, RACIAL

Attitude is one of the oldest concepts in the field of social psychology, but its proper meaning has often remained obscure. The basic understanding has been that, when presented with an “object of thought” regarding a person, group, policy, or idea, an individual will possess an attitudinal judgment on a scale of favorableness. However, this definition is contested; others argue that attitudes are much more complex cognitive structures than simple judgments regarding an object of thought (e.g., van Dijk 1987). Nevertheless, social psychologists most often use the former definition and measure racial attitudes, and how they change over time, using survey methods. In many ways, this dominant form of measurement downplays the complexity within people’s belief systems.

PROBLEMS WITH MEASUREMENT

The study of racial attitudes arose in the 1930s from concerns over anti-Semitism and the European Holocaust. The first major study of racial attitudes linked individual possession of anti-Semitic views with authoritarian personality traits (Adorno et al. 1950). These early researchers conceptualized racist views as stemming from the larger society but as choice items a person could choose to either adopt or decline, based on one’s psychological needs. The continued focus by social psychologists on individual characteristics of the attitude-holder has been criticized, because the historical, social, and rhetorical aspects of the attitudes are often ignored. In other words, thinking itself is a cultural product rather than an individual process, which emerges from a certain social context (Billig 1991).

The most well-known, comprehensive study of racial attitudes in the United States analyzes changes in survey data from the early 1940s until the mid-1990s (Schuman et al. 1997). The findings show a consistent liberalization of racial attitudes of white Americans toward African Americans. One major problem with this and other studies of racial attitudes is that much of the alteration in survey responses over time could be attributed to changes in social norms, not necessarily attitude changes.

A related problem occurs when old survey questions are reused for the sake of longitudinal analysis, but, eventually, their relevance diminishes. All questions are created within a certain context, and the social environment inevitably changes over time. For example, a question asked throughout six decades in the United States is: “Do you think white students and Negro/black students should go to the same schools or to separate schools?” This question found nearly 70 percent in favor of separate schools in 1942, and by 1996, decades after the matter had been settled by federal law and public schools were integrated, only 4 percent retained a preference for separate schools—to which they would admit when surveyed.

Some changes in attitude trends can be attributed to changing social norms, but it is likely that another significant factor in the apparent liberalizing trend is people learning how to express themselves in a way that will prevent them from sounding racist. In a society like the United States, where being a “racist” is now equated with being a bad person, many people try to avoid sounding racist, even if they do hold some strong, prejudiced views (Bonilla-Silva 2006).

Traditionally, attitude theorists see the views that people express in surveys as representing the inner thoughts and feelings of respondents. Rather, in people’s talk there is evidence that responses to abstract objects (“blacks”) rely on specifics (e.g., marriages between whites and blacks)—the context of the question in the discussion or the particular social issues of the day. Additionally, people express their views in much more complex ways than can be predicted by traditional attitude theory (e.g., Billig 1991; Potter and Wetherell 1987; van Dijk 1987). For example, an initial positive reflection on the object of thought may in actuality be a disclaimer, after which the individual, if allowed, will explain why they do not actually feel completely favorable on the issue (Potter and Wetherell 1987; Bonilla-Silva 2006). Because of this, survey responses may be better viewed as discursive acts instead of attitudinal expressions, and they should be used in conjunction with in-depth interviews whenever possible.

However, there are additional factors to consider within the more in-depth interview format. For example, how the question is framed will affect the respondent’s interpretation; the object of thought may not be consistent between researcher and respondent (Potter and Wetherell 1987). Additionally, whether it is within the format of a survey, interview, or focus group, the researcher (a stranger) may not put respondents sufficiently at ease to answer openly in an artificial environment.

ATTITUDES AND BEHAVIOR

A final critique of racial attitude research is that the correlation between attitudes and behavior is indirect and unclear (Fishbein and Ajzen 1975). Research frequently finds inconsistencies between people’s behavior and their stated attitudes. One major factor in this dynamic is that behavior arises not simply from attitudes but is also
shaped significantly by social norms (van Dijk 1987). “Social behavior is controlled to a considerable extent by exactly the same norms that control the expression of attitudes in surveys, and one should not look to either for final evidence of what goes on in the hearts of men and women” (Schuman et al. 1997, p. 7). Thus, even when there is consistency between behavior and expressed attitude, there is no assurance that the attitudes themselves are dictating the behavior. Furthermore, there is evidence in social psychological research that one’s behaviors can affect attitudes and feelings; people observe their own behavior and make inferences about their internal motivation for such acts.

How important are racial attitudes if their correlation to behavior is not direct? From the perspective of those experiencing racial oppression, gauging the internal feelings of oppressors may not seem nearly as important as understanding, in a practical way, the behaviors of racially dominant group members. From this understanding, strategies may be devised to challenge the way dominant groups treat subordinate groups. These are the tangible battles that can be fought in courtrooms—places where people are held accountable for their actions, not their attitudes, or emotions, or fears, which they may or may not reveal to others, no matter the circumstances.

**ATTRACTION**

**SEE** Similarity/Attraction Theory.

**ATTRIBUTION**

It is important to understand why things happen in order to control outcomes or prevent future undesirable occurrences. *Attributions* answer the question of “why” something happens. People tend to seek attributions for unexpected events, and generally infer that things happen either because of factors internal to the actor (personality or dispositional factors) or because of situational influences.

This distinction between situational and personality attributions can be traced to Fritz Heider’s seminal book, *The Psychology of Interpersonal Relations* (1958). Heider further identified a stability dimension of attributions. That is, stable situational forces, such as test difficulty, can cause outcomes—but so too can unstable forces, such as a chance opportunity for cheating. Personality can be conceptualized similarly. Stable personality factors include such forces as ability or intelligence. Examples of unstable personality factors are motivation and effort, both of which can change over time and across situations.

Inspired in part by Heider’s ideas, Edward Jones and Keith Davis (1965) developed *correspondent inference theory* (CIT) to predict whether observers of an event will make personality or situational attributions for the actor’s behavior. According to CIT, the more clearly a person has freely chosen to do something unexpected, and the more clear the intended effects of the activity are, the more likely perceivers are to make personality attributions. When free choice of behavior is limited, when the behavior is not perceived to depart from the norm, and when the intention of the behavior is unclear, perceivers are less likely to make personality attributions.

Another early attribution theory based on Heider’s work is Harold Kelley’s *covariation theory* (1967). This theory explains that effects are attributed to causes with which they “covary.” That is, perceived causes will differ, depending on whether or not an effect is associated uniquely with a particular object, a class of objects, or other people. If a person were happy after seeing a movie, one would attribute the happiness to the person’s liking of that particular movie. However, if one knew this person...
was happy after most movies, one would attribute the happiness to the person being a movie buff.

Given the complexity of the reasoning involved in making attributions in accord with Jones and Davis’s and Kelley’s notions, it is not surprising that attributions do not always follow theoretical predictions. Such departures often are referred to as attributional biases. Well-known biases include the fundamental attribution error (FAE)—the tendency to overestimate personal, and underestimate situational, causes for behavior—and the actor-observer effect, or the tendency to commit the FAE more strongly when explaining others’, rather than one’s own, behavior. Additionally, the self-serving bias, identified by Gifford Weary Bradley in 1978 as reflecting self-esteem concerns, is the tendency of people to attribute good outcomes to causes that are internal, do not change over time, and have global implications for success in other areas. When bad things happen, however, people tend to invert this pattern. They attribute failures to external, temporary causes that have few implications outside of the specific context they take place in. All together, much research has focused on attributional biases. Together with an understanding of past theories, new findings permit ever more accurate models of how people ask “why?”

HISTORY OF AUCTIONS
Auctions have been used since antiquity and have a colorful history. One of the earliest written records of an auction is a description by Herodotus and dates back to 500 BCE (see Cassady 1967, p. 26). At that time in Babylon, women were sold annually as brides in auctions. Auctions were also used in ancient Rome for commercial trade and for the sale of almost anything from slaves to plundered booty and debtor’s property. Martin Shubik (1983) provides an entertaining sketch of the history of auctions in the Roman and Babylonian empires, while Ralph Cassady Jr. (1967) discusses the types of auctions used in England and America in the seventeenth and eighteenth centuries and the establishment of the world-renowned auction houses Sotheby’s and Christie’s.

STANDARD AUCTION TYPES
Despite the variety of auction methods, only four basic types of auctions are commonly used: the ascending bid auction, the descending bid auction, the first-price auction, and the second-price auction. In the ascending-bid auction (also called English or open outcry auction), the price is successively raised until only one bidder remains, and that bidder wins the auction at the final price. This auction form is most familiar to the general public and is usually used to sell art and other collectibles. In the descending-bid auction (also called Dutch auction, as it has been used for the sale of flowers in the Netherlands), the auctioneer starts at a very high price. The price is gradually lowered until one bidder accepts paying the current price for the auctioned item. This auction is commonly used to sell perishables like fish or flowers. In the other two standard auction formats—first-price sealed bid and second-price sealed bid auctions—bids are submitted in sealed envelopes. In both sealed bid auction formats, the winner is the person with the highest bid. The auctions differ in their payment requirements, however: In the first-price auction, the winner pays the amount they have bid; in the second-price auction, the winner pays the second-highest bid. These auctions are most commonly used for procurement of government contracts.
Auctions are market institutions with well-defined rules that determine how the winner is selected and what the payments are, depending on the bids. For that reason auctions are typically modeled and analyzed as bidding games of incomplete information. The first treatment of auctions, which identified the strategic aspect of bidding, is found in the work of William S. Vickrey (1961). Vickrey assumed that each bidder knows precisely how highly he values the item, but does not know anyone else’s valuation of the item. The other bidders’ valuations are perceived to be uncertain; they are drawn from the same probability distribution and are stochastically independent. All bidders are considered risk neutral. Vickrey’s major contribution is the celebrated revenue equivalence theorem. It states that under the above premises all four auctions generate the same average revenue for the seller. His model is known as the independent private value model and is well suited to situations in which consumers buy an item for their own use. If the item is bought for the purpose of resale, however, it has a single, objective value (the resale value), though bidders may have different guesses about what this value would be. To analyze such a situation, one would need to employ a common value model. The most general treatment of the auction problem, which allows for interdependence among bidder’s valuations and includes the common value and the private value models as special cases, was developed by Paul R. Milgrom and Robert J. Weber (1982). This entry will establish a revenue ranking for the four standard auction formats, and show that on average, revealing information about the quality of the item put up for sale increases equilibrium bids and, consequently, seller’s proceeds.

The purpose of auction theory is twofold. On the one hand, auction theory attempts to explain the existence of certain trading institutions and the functioning of the price formation and exchange processes. On the other hand, it provides a guide on how to tailor the trading mechanism to certain information environments and suggests improvements in already existing institutions. A line of inquiry of both practical and theoretical interest is the design of optimal auctions—auctions generating the highest expected revenue for the seller. In an influential paper, Roger B. Myerson (1981) introduced a method that allows one to design the best-performing trade mechanism for a wide class of environments. Jeremy I. Bulow and D. John Roberts (1989) made Myerson’s approach accessible to a much broader audience of economists by recasting it in terms of marginal revenues and marginal cost and linking it to the theory of monopoly pricing. The theoretical work on auctions continues to grow rapidly—by December 2006 the Econ Lit Database contained more than two thousand entries with the words auction or auctions, about half of them theoretical.

**AUCTION EXPERIMENTS AND COMPUTER SIMULATIONS**

Experimental studies of competitive bidding in auctions first appeared in the early 1980s, with a primary focus on testing the theoretical properties of the standard auction formats. The experimental results established several facts about behavior relative to the theoretical predictions. For instance, the revenue equivalence theorem concerning private value auctions fails in the laboratory. Bids in first-price auctions are higher than in Dutch auctions and bids in second-price auctions are higher than in English auctions. These results remain consistent when the number of bidders is changed. The comparative static predictions of the equilibrium model, however, remain valid. Bidders with higher valuations bid higher and bids generally increase with an increased number of bidders. This picture changes in common value auction environments. In a common-value auction, bidders face a more complicated strategic problem because such auctions involve a combination of competitive bidding and value estimation. Inexperienced bidders often fall prey to the winner’s curse. The bidder who ends up winning the auction has the most optimistic estimate of the value of the auctioned item. This leads to excessively high bids and to winners who pay prices higher than the value of the item on sale. John H. Kagel (1995) provides a comprehensive overview of the experimental literature on auctions. The use of computer simulations to study the performance of market institutions has been proposed by researchers on the crossroad between economics and engineering (for a discussion, see Roth 2002.)

**ONLINE AUCTIONS: PHENOMENA AND PSYCHOLOGY OF BIDDING**

Since the 1990s online auction sites have been a popular place to trade a variety of goods. By far the most popular online auction site is eBay, which was founded in 1995 and has evolved from a simple online mechanism for buying and selling collectibles to a major marketplace, where in 2001 about $9 billion worth of goods were traded. This is three times more than, for instance, the total sales of Amazon for that year. A phenomenon widely observed on eBay is the tendency of bidders to submit bids in the last seconds of bidding. (This phenomenon, called last-minute bidding or sniping, is pertinent only to eBay-style auctions, which have a predetermined deadline. Amazon-style auctions do not have a hard close. Rather, they have an automatic extension rule that allows bidding to continue if bidding activity is registered in the last ten minutes of an auction.) Explanations for the practice of last-minute bidding have fallen into two categories. One idea, advanced by Patrick Bajari and Ali Hortacsu (2003), attributes this effect to the existence of experts, who wait until the very
Audits for Discrimination

end of the auction because they do not want to reveal their interest in the item on sale. This argument is valid for common value auctions where expert opinion matters. The late bidding phenomenon also exists in private value auctions and Roth and Axel Ockenfels (2006) provide another rationale for bidding close to an auction's end in these circumstances. Waiting until the end allows bidders to acquire an item at a lower price by preventing “bidding wars” (the successive escalation of bids). Other issues of interest to both psychologists and economists are the effect of minimum bid and secret reserve prices on bidding behavior. Bajari and Hortacsu (2004) provide an extensive review of the economic research on Internet auctions.

AUDITS FOR DISCRIMINATION

An audit is a survey technique that isolates the impact of a person’s group membership on the way he or she is treated in the marketplace. Audits, also called tests, first appeared in the 1950s. Since then they have been used to study racial, ethnic, or gender discrimination in car sales, hiring for entry-level jobs, home insurance quotes, preapplication treatment in the mortgage market, house sales, and apartment rentals. National audit studies of housing discrimination were conducted in the United States, for example, in 1977, 1989, and 2000, and audits have been used to help enforce civil-rights laws, particularly in the housing market.

AUDIT METHODOLOGY

In an audit study, people from two groups are selected, trained, and paired so that they are equally qualified in the market being studied. Audit teammates may be equally qualified to buy a house or a car, for example. One member of the team belongs to a legally protected minority group and the other belongs to the comparable majority group. A sampling frame, such as newspaper advertisements, is then selected; a sample is drawn; and an audit is conducted for each observation in the sample. Audit teammates paired for an observation successively visit the associated economic agent, usually in random order, to engage in the relevant market activity, such as applying for a job or inquiring about an available apartment. Each teammate then independently records how he or she was treated. Discrimination exists if minority auditors are systematically treated worse than their teammates. Most audit studies observe several types of agent behavior; discrimination may exist for some types and not for others.

Audits are an alternative to regression studies, which use statistical procedures to determine whether some economic outcome is less favorable for people in a minority group, after controlling for relevant individual characteristics. This approach leads to biased results if key characteristics are omitted from the regression. An audit study minimizes the possibility of omitted-variable bias by matching similar individuals; giving them the same training; assigning them similar or identical characteristics, such as income or education, for the purposes of the audit; and sending them to visit economic agents in
response to the same advertisement within a short time of each other. These procedures ensure that audit teammates do not differ significantly in terms of any characteristic, other than group membership, that might influence their treatment in the marketplace.

Audit studies face many challenges of design and management. Researchers must decide, for example, whether audits should be “blind” in the sense that teammates are unaware of the purpose of the study or that they have a teammate. Some scholars believe that this step is needed to protect the integrity of audit results. Discriminatory treatment is sometimes so egregious, however, that it can upset auditors to the point of compromising their ability to fill out the audit survey forms. To preserve the accuracy of the audit information, therefore, it sometimes makes sense to tell auditors the purpose of the study and train them to fill in the forms as objectively as possible, no matter what happens during the audit.

Audit results must be interpreted with care. An audit study indicates the discrimination that occurs when members of a certain minority group with certain assigned traits visit a random sample of economic agents identified through a particular sampling frame. Because discrimination may not be the same under all circumstances, however, the discrimination experienced by the average member of a group may not be the same as the differential treatment of that group in an audit study. Moreover, audit studies do not provide comprehensive measures of discrimination, but instead measure discrimination only in certain types of behavior, and they may not be feasible for complex market transactions.

Audit studies also face challenging statistical issues. Different statistical procedures are required to measure discrimination for different types of agent behavior, for example, and statistical tests need to recognize that some factors relevant to the treatment of auditors, such as the skill or mood of the agent being audited may be shared by teammates but not observed by the researcher. In addition, audit studies must recognize that people in a legally protected minority are sometimes favored, for either systematic or random reasons. This fact leads to two different measures of the incidence of discrimination, which serve as upper and lower bounds. The gross incidence of discrimination is the share of audits in which the nonminority auditor was favored. The net incidence is the gross incidence minus the share of audits in which the minority auditor was favored. The net incidence measure is accurate if all favorable treatment of minority auditors is due to random factors, so that subtracting this favorable treatment is a correction for randomness. Minority auditors might be favored for systematic reasons, however. Systematic favoring of minority auditors is troubling in its own right, of course, but it should not be subtracted from gross incidence to determine systematic unfavorable treatment of minorities; a real estate broker who refuses to show any houses to black customers is discriminating regardless of whether or not another broker fails to show white customers any houses in black neighborhoods.

Finally, audit studies raise ethical questions because they make demands on economic agents, including many agents who do not practice discrimination. In 1982 the U.S. Supreme Court decided in 

\[\text{Havens Realty Corporation vs. Coleman}\]

that housing audits are a legitimate investigative technique. Nevertheless, scholars conducting audits have a responsibility to make certain that their studies are well managed and do not make unnecessary demands on the economics agents being audited.

RESULTS FROM AUDIT STUDIES

Audit studies have uncovered racial, ethnic, and gender discrimination in several countries. Recent audit studies in the United States have found discrimination against blacks and women in car sales, against blacks and Hispanics in hiring for entry-level jobs, against women in hiring for servers at expensive restaurants, and against blacks and Hispanics in preapplication mortgage procedures. The 2000 national housing audit study found, among other things, that both blacks and Hispanics receive less information about available housing units than do non-Hispanic whites in both the sales and rental markets. In the sales market, for example, white auditors but not their black teammates were shown additional units similar to the advertised unit in 22.9 percent of the audits (gross incidence), whereas black auditors were favored over their white teammates on this measure of treatment in 16.0 percent of the audits. The difference between these measures, 6.9 percent, is the net incidence of discrimination.

Not all audit studies find discrimination, however, and some audit studies find that certain types of discrimination are declining. An audit study of the home insurance industry, for example, found no clear evidence of discrimination. Moreover, a comparison of the results of the 1989 and 2000 national housing studies reveals significant declines in many types of discrimination, including several associated with housing availability. This comparison also reveals increased discrimination against blacks and Hispanics in some other types of agent behavior, including the number of housing units shown and steering, which is defined as directing different customers to different types of neighborhoods based on their race or ethnicity. Real estate agents were more likely, for example, to steer black customers away from white neighborhoods in 2000 than in 1989.

Finally, audit studies provide some insight into the causes of discrimination. One study found, for example,
Austrian Economics

that the more expensive a house, the more likely it is to be withheld from black customers. Because black and white teammates in this study had the same qualifications and made the same requests, this result suggests that some real estate brokers act on the basis of a stereotype that black households cannot afford expensive houses, rather than on the basis of a customer’s stated income and wealth.

AUSTRIAN ECONOMICS

Austrian economics, so named for its country of origin, is distinguished by its methodological precepts and by its theories of capital, money, and the business cycle. Carl Menger (1840–1926), who taught at the University of Vienna, is the acknowledged founder of this school of thought. Menger’s writings, particularly his Principles of Economics (1871) and his Investigations into the Method of the Social Sciences (1883), set out the principles and methods that guided the development of a worldwide Austrian tradition.

Menger rejected the German historicism of Wilhelm Roscher (1817–1894), which offered an inductive approach to economic understanding; and he deviated markedly from the eighteen-century British classicism of David Ricardo (1772–1823) and John Stuart Mill (1806–1873), which featured long-run relationships among the different economic classes of people (workers, capitalists, and landlords). Menger’s theory of economic institutions does bear a striking resemblance to the invisible-hand theorizing of Adam Smith (1723–1790). However, given Smith’s cost-based theory of value, the appropriateness of linking Menger and his followers to the reputed father of economic science is a contentious issue among contemporary Austrian economists.

Menger focused on the individual market participant and on his or her choices as governed by perceived needs and wants. This general approach to economics was termed methodological individualism by the sociologist Max Weber (1864–1920). Menger’s notion of economic value derives from the purposes of the individuals doing the valuing rather than from the qualities of the objectively defined goods being valued. Menger’s value theory, termed methodological subjectivism and now embedded (though not consistently) in modern economics, stood in contrast to Marxism’s labor theory of value and classicism’s cost-of-production theory of value.

Methodological individualism and the closely related methodological subjectivism allow for a straightforward accounting of the gains from trade. Individuals value various goods differently, such that trading goods allows both traders to gain. Direct exchange (goods for goods) leads quite naturally to indirect exchange (goods for more-easily-tradable goods for actually-sought-after goods). The more-easily-tradable goods are called media of exchange. Over time, the practice of indirect exchange gives rise to a most commonly accepted medium of exchange. This is Menger’s theory of money—with early monies taking the forms of salt or cattle and later monies, silver or gold. (The fact that modern paper money is a result of governmental institutions overriding the would-be choices of market participants is seen as supporting Menger’s theory.)

Whether exchange is direct or indirect, market values never pertain to the whole of the supply, such as the diamond supply or the water supply. Rather, they pertain to the smallest quantities of the goods subject to potential trades, that is, the marginal unit. Because of relative scarcities, the value of the marginal unit of diamonds exceeds the value of the marginal unit of water—despite water’s being the more useful of the two goods. This is Menger’s resolution of the so-called diamond-water paradox, which was identified by Adam Smith (who distinguished value in use from value in exchange) but not satisfactorily resolved until the “Marginalist Revolution” of the 1870s. Menger was one of three revolutionists, the others being British economist William Stanley Jevons...
(1835–1882) and French economist Leon Walras (1834–1910). The latter two formulated the issues mathematically by writing the equations for total and marginal utility (Jevons) and for the equilibrium relationships among all the prices in a frictionless market economy (Walras).

Historians of economic thought sometimes see the Austrian theory as applying only to the demand side of the market—with supply and demand finally being juxtaposed by Alfred Marshall (1842–1924), who drew supply from the classicists and demand from the marginal revolutionists. But Menger applied his value theory to the means of production as well as to the ends. Consumption goods were designated as goods of the first order. Markets for goods of the second, third, and higher orders guide the time-consuming production activities that proceed from the highest to the lowest order. This reckoning, together with the concept of opportunity costs introduced by Friedrich von Wieser (1851–1926), established the Austrian supply-side relationships.

Eugen von Böhm-Bawerk (1851–1914) developed Menger's conception of the production process into a theory that he explicated in Capital and Interest (vol. 2, 1889). The rate of interest governs the extent to which resources can profitably be tied up in the production process: The lower the interest rate, the more roundabout, or time-consuming, the production process. Unfortunately, Böhm-Bawerk's use of a crude arithmetic reckoning of roundaboutness (the average period of production) diverted attention from the otherwise Mengerian construction and played into the hands of critics who questioned the relevance of such a metric.

In his Theory of Money and Credit (1912) Ludwig von Mises (1881–1973) used marginalist thinking to account for the value of money and, drawing on Böhm-Bawerk's capital theory, set out a theory of the business cycle. Interest rates held artificially low by central banks stimulate investment and cause production processes to be unduly roundabout. In the absence of sufficient resources to complete all of the production processes, the boom eventually gives way to a bust. In essence, the boom-bust cycle is an instance of economic discoordination attributable to an interest rate that does not accurately reflect the valuations and choices of market participants.

Mises systematized Austrian economics in his Human Action (1949), calling its method praxeology, which literally means "action logic." He distinguished between economics and history, denying that there is a unilateral testing of economic theory with historical data but recognizing that the two disciplines are essential complements in our understanding of real-world economies. Mises's praxeology, an exclusively deductive system of logic based on self-evident axioms (e.g., human action is purposeful), stands in contrast to Milton Friedman's "methodology of positive economics" (1953), according to which contrary-to-fact assumptions can be used in the formulation of theory, which can then be accepted or rejected on the basis of empirical evaluation. In Mises's hard-drawn Austrianism, empirical studies serve to identify cases or episodes in which a particular theory is applicable.

In his Prices and Production (1935), Friedrich A. Hayek (1899–1992) developed the business-cycle theory, offering this means-ends theorizing about booms and busts as an alternative to the circular-flow theorizing of John Maynard Keynes (1883–1946). By many accounts, Hayek's theory lost out to Keynes's primarily because of its lack of politically attractive policy prescriptions. Israel M. Kirzner (b. 1930) developed the essential entrepreneurial aspects of the Austrian theory and, along with Hayek, offered a market-as-a-process view that stands in contrast with the more conventional mathematics of market equilibria. In both microeconomic and macroeconomic contexts, the Austrians have argued that governments are ill-advised to override market forces with central planning or to supplement those forces with economic stimuli. The policy prescription of laissez-faire is emphasized by Murray Rothbard (1826–1995) in his Man, Economy, and State (1962).

Through his introduction and selection of articles, Israel Kirzner offers, as an Austrian sampler, a three-volume Classics in Austrian Economics (1994). Dating from the mid-1970s, numerous books and articles have made Austrian economics a living tradition. Some developments and extensions are intended to compete with modern mainstream thinking; others to reconcile with it. In the contemporary world of economics, the Austrian principles of microeconomics (the subjectivity of value and opportunity costs) are widely accepted, although they are often observed in the breach because of considerations of mathematical tractability and data availability. By contrast, Austrian macroeconomics, which is rooted in capital theory and focuses on the allocation of resources over time, has been neither widely accepted nor well understood. Dating from the Keynesian revolution, capital theory is seen as foundational for theories of economic growth but as largely irrelevant for macroeconomics, which deals instead with overall levels of output and inflation.

AUSTRO-MARXISM

The term Austro-Marxism was probably introduced by the American socialist Louis Boudin to characterize a specific Austrian version of Marxism. Established at the turn of the twentieth century, Austro-Marxism became a powerful political and cultural movement during the Austrian First Republic (1918–1934). For analytical purposes, Gerald Mozejć (1987) distinguishes three versions of Austro-Marxism. First, there was the political Austro-Marxism put forth by political intellectuals such as Otto Bauer, Karl Renner, Rudolf Hilferding, Max Adler, and Friedrich Adler. This version represents what might be called a third way of thinking, located between (or beyond) socialist revisionism and Leninism. It was more radical than the First Socialist International as well as more democratic (or moderate) than the Bolshevik approach to Marxism. In contrast to other Marxist conceptions, Austro-Marxism was not based on Hegelian dialectics but on two rather distinctive philosophies: the materialism of natural scientist and philosopher Ernst Mach (1838–1916), and the idealism and ethics of Immanuel Kant (1724–1804).

Second, there was Austro-Marxism as scholarship. Outside the universities that were dominated by conservatives, and even suffused with anti-Semitism, there were institutions offering extramural teaching and adult education at which a large number of socialist intellectuals were active in various academic disciplines, such as economics, law, sociology, history and, last but not least, the natural sciences. Their institutional and personal cooperation established interdisciplinary work and combined scholarship with political commitment and activism. A number of scholars and social scientists, such as Otto Neurath, Paul Lazarsfeld, and Marie Jahoda, worked in this particular context, which has been referred to as an “alternative institutionalization” of social sciences and cultural studies (cf. Sandner 2006).

Third, mention must also be made of Austro-Marxism as a way of life. Austrian socialism was organized into a number of political and cultural associations that claimed to establish within bourgeois society a counter-culture based on socialist values and attitudes, such as solidarity, class consciousness, and the socialist reform of everyday life.

In a way, Austro-Marxism was the political theory of the socialist camp (in contrast to the Catholic-conservative and the pan-German camps), although not all Austrian socialists were Austro-Marxists. However, Austro-Marxism existed not only on a theoretical level; it was closely connected with the socialist counterculture in “Red Vienna” (the socialist-governed capital of Austria) between 1918 and 1934 (cf. Gruber 1991; Rabinbach 1983, 1985). In certain political fields, such as housing and adult education, its practitioners were able to bring about remarkable improvements in the social and cultural conditions of the working class.

Theoretical Austro-Marxism’s rather nondeterministic and undogmatic approach enabled it to broadly partake of and to absorb modern intellectual currents—including psychoanalysis and empirical sociology—and led to a wide-ranging intellectual exchange, even among nonsocialist politicians and scholars. In actual practice, both its strict parliamentary strategy and the socialist-governed Red Vienna project worked successfully for a long period. It eventually collapsed, in contrast to other socialist-oriented experiments, through no fault of its own (i.e., undemocratic practices), under the weight of the violent policies of Austro-Fascism (1934–1938) and National Socialism (1938–1945). By the end of World War II, most of Austro-Marxism’s representatives were dead, while the majority of those that emigrated did not return to Austria.

Authoritarianism

Authoritarianism is one of the three main types of political systems (or regimes), democracy and totalitarianism being the other two. Social science scholars have identified a number of features of authoritarianism in its ideal type form. The ideal criteria may not be present in practice in actually existing authoritarian systems. Rather, descriptions of the ideal type provide a measuring stick for analysts to assess how authoritarian a particular system is. Scholars also increasingly recognize a hybrid between authoritarianism and democracy as forming its own ideal type regime, generally called either semi-authoritarian or semi-democratic systems (Ottaway 2003).

Defining Features of Authoritarianism

Defining features of authoritarianism include the existence of a single leader or small group of leaders with ultimate political authority. Believing in the supremacy of the authority of the state over all organizations in society, authoritarian leaders make all important government policy decisions. The state’s needs are paramount; individualism is encouraged only to the extent that it benefits the state. Ideal type authoritarianism lacks both official and unofficial limitations on its power, although Mark Hagopian (1984, p. 118) has argued that, in practice, powerful social groups can maintain unofficial, “extralegal” constraints over authoritarian leaders.

Whereas totalitarianism strongly emphasizes an official and overarching ideology serving as a blueprint for the remaking of society, authoritarianism is less concerned with ideology. When authoritarian leaders come to power, they often have a set of policy goals—such as eliminating corruption or resurrecting the economy—as well as what Juan Linz (1975) calls a “mentality” about the purpose of their rule. But this is quite different from the kind of ideology present in an ideal type totalitarian system.

Authoritarian systems commonly emerge in times of political, economic, and social instability, and thus, especially during the initial period of authoritarian rule, authoritarian systems may have broad public support. The stereotype of an authoritarian leader as uniformly despised by the general population is rarely accurate. In the majority of authoritarian systems, however, these public (and publicly supported) goals take a back seat to the maintenance of the regime’s power if the latter is threatened. Over time, if the government fails to achieve its policy goals, the public may withdraw its support.

Because of the government's control of the state's repressive mechanisms, declining support need not translate into popular unrest and antigovernment mobilization. Indeed, another of authoritarianism's defining features is the limiting of mass political participation. Democratic and totalitarian systems encourage the general public's political participation, although in the totalitarian case the state or ruling party controls all aspects of mass political mobilization. Authoritarian leaders typically prefer a population that is apathetic about politics, with no desire to participate in the political process. Authoritarian governments work to develop such attitudes, both by fostering a sense of a deep divide between society and government and by repressing expressions of dissent, violently if necessary. Consequently, authoritarian leaders view the rights of the individual, including those considered to be “human rights” by the international community, as subject to the needs of the government. Concern about the possible emergence of potential political opposition can become an obsession of authoritarian leaders, weakening their effectiveness as leaders and the policy performance of the government.

Types of Authoritarianism

Just as social scientists identify various types of democratic systems, scholars highlight three types of authoritarianism. A military authoritarian system is one in which the military is not only privileged—as it typically is in all authoritarian systems—but actually in control of all major aspects of government decision-making. The rule of
Augusto Pinochet in Chile from 1973 to 1988 is the classic example of a military authoritarian regime.

In party authoritarian systems, on the other hand, a single political party dominates the system. Though this is also true of totalitarian systems (e.g., Stalin’s USSR or Hitler’s Germany), party authoritarian systems penetrate into society less than totalitarian systems. Party authoritarian systems may even tolerate small opposition parties and use mechanisms of democracy like elections in an effort to increase their legitimacy with the public. Mexico’s authoritarian system prior to the reforms of the 1990s and 2000s is an example of a party authoritarian system.

Bureaucratic authoritarian systems are run by the military but rely heavily on experts in the fields of economics and other policy areas, often allowing them significant autonomy to set and oversee government policy. Social scientists often label these officials technocrats. Military leaders point to the technical expertise of these bureaucrats as a key component of their economic modernization policies, which are introduced under harsh authoritarian conditions to prevent opposition to economic reforms. Guillermo O’Donnell identifies Argentina from the mid-1960s to the mid-1970s as the classic example of bureaucratic authoritarianism.

**AUTHORITY**

In the first volume of *Economy and Society* (1978), Max Weber defines authority as the belief in the legitimacy of individuals to exercise power, such that they are able to influence others to do their will even with resistance, and a specific group will likely follow those orders.

Weber develops a schema of legitimate authority, identifying three pure forms. Legal authority, sometimes referred to as rational authority, is based on rules and laws. Under these laws, people have the right to exercise authority through the office they occupy. It is the position itself that holds authority, with obedience being owed to the office, such as chief executive officer or the presidency. The office continues to hold authority after the officeholder vacates it. Traditional authority is based on tradition or custom. Obedience is owed to individuals such as tribal leaders or kings through tradition. When the individual vacates the position, tradition determines who will fill the position. Finally, charismatic authority is based on dedication to the extraordinary personality of an individual and the standard or norm he or she establishes. Obedience is owed to the individual charismatic leader. Weber considered charismatic authority to be a revolutionary force in that it renounces tradition and submission is guaranteed through proof or the display of a miracle.

Jürgen Habermas notes the importance of discourse, or speech, as it relates to authority. Mark Warren (1995) recounts Habermas’s argument that authority is created through discourse, particularly in those settings that prevent other forms of authority from intruding. Through discourse, citizens in a democracy make known the issues that concern them and are able to understand others. The result is a form of consensus by which laws are created and normative changes are instituted.

Theodor Adorno and colleagues, in *The Authoritarian Personality* (1950), notes that an individual’s submission to the authority of a parent may be linked to submission to authority in general. In particular, he finds that opposition toward parents’ authority is often evidenced as resistance to authority in general. As a result of this study, Adorno identified an authoritarian personality type. As James M. Henslin (2005) summarizes, this individual is highly prejudiced against minority groups, while also being highly conformist and respectful of authority.

Ralf Dahrendorf, in *Class and Class Conflict in Industrial Society* (1959), identifies authority in relation to class. One class exercises authority in industry yet may also be subject to authority from others. Others are sub-
ject to authority from supervisors but do not exercise their own authority. The classless do not exercise authority and are not subject to authority, such as independent workers. Thus, class is determined by the degree of authority one holds. Since industry plays a large role in one's life, a person's authority may be influential in other spheres, including the family.

Stanley Milgram (1974) experimentally tested individual obedience to authority. Authority is contextual in nature, meaning that a person with authority in one situation will not necessarily have the same authority in another. Authority comes from a person's power in a social situation, not from personality. In certain situations, there is an expectation that an authority will exist. The authority becomes apparent through (1) self-identification of the individual with authority; (2) external objects, such as uniforms, identifying the individual as an authority; (3) the lack of a competing authority; and (4) the lack of obvious inconsistencies. In his infamous shock experiments, Milgram found that individuals, who may have protested against the shocking of individuals, were willing to continue with the experiment when an authoritative individual encouraged them on.

Organizational theory has further developed the notion of authority. Philippe Aghion and Jean Tirole (1997) note the distinctions between formal and real authority. They define formal authority as “the right to decide” while real authority is defined as “the effective control over decisions” (p. 1) with the former not necessarily granting the latter.

AUTOCRACY
From the Greek word autokratôr meaning self-ruler, or ruler of oneself, the term autocracy refers to one-person rule, or a government led by a single person with unlimited power. The autocrat has uncontrolled and undisputed authority over the people and others in the government, controlling all aspects of social, economic, and political life. Autocracies come in two forms: an inherited autocracy is also referred to as a monarchy while a nonheredity
Autocracy is a dictatorship. Autocracy is often used interchangeably with the terms despotism, tyranny, and dictatorship.

Autocracies did not develop in a formal way until the emergence of the state. Human culture has experienced four basic political organizations: bands, tribes, chiefdoms, and states. Band societies are characterized by being nonstratified, essentially egalitarian, kin-based groups whose leadership is based on ability. They are highly local and, because they are kin-based, have very small membership groups. Decision-making in band society is typically done by consensus, meaning that members of the group discuss an issue until everyone agrees on a particular course of action. Tribes are larger, more regionalized groups that share many of the characteristics of bands with the exception of size. As regionalized groups, tribes are linked together and often act together in times of conflict or need. Chiefdoms and states, unlike bands and tribes, are hierarchical or stratified. The head of state or chief rules by the power of their office and can command armies and exact tribute (taxes are a form of tribute). The difference between chiefdoms and states is that chiefdoms are kin-based while states are bureaucracies. Bureaucracies are formalized public bodies that perform particular tasks such as law-making. Chiefdoms and states have large memberships and leaders may not have direct contact with most of their followers or members. Members may also have no authority in choosing those who are in positions of leadership. This is generally the case with an autocratic form of government.

In Roman times the terms imperator, Caesar, and Augustus were used to signify an autocratic form of government. Autokratôr was often used in place of imperator. Perhaps the best example historically of an autocracy would be the Russian Czarist (Tsarist) system of government. The czars were referred to as Imperator i Samodyerzhets Vserossiysky, which translates as “all-Russian emperor and autocrat.” Late-twentieth-century forms of autocratic rule (though often challenged by subjects) include the government of Saddam Hussein in Iraq. Hussein, a member of the Ba’ath party, often ruled Iraq through intimidation and acts considered to be crimes against humanity. Because of this, many people in Iraq lived in fear, many were executed and murdered, and many others rose to positions of power within his government. This contrasts with other forms of government such as democracies in which leadership is decided by the people and where there are clear limits on the power of the chief executive and members of the government. The United States is technically a democracy, but is administered as a republic, wherein representatives are elected to serve the people in the House of Representatives and the Senate. There are three branches of government: the executive branch (president and the cabinet), the judicial (Supreme Court and federal court system), and the legislative (House and Senate). This configuration is designed to prevent any single branch of government from wielding too much power, including that of the executive branch and the president. Despite this, the president holds the power of veto, wherein decisions of the other branches may be overruled, and the president may also make decisions in times of emergency without consultation with or support from the other branches of government. Ultimately, this power could lead to autocratic-like authority. In the twenty-first-century United States, President George W. Bush has been compared to an autocrat in some of his decisions regarding the Iraq War, the imposition of a democratic-style government in Iraq, and in his relationship with the other branches of government in the United States.

AUTOKINETIC EFFECT

The autokinetic effect is an optical illusion. It occurs when a perceiver staring at a stationary pinpoint of light in an otherwise completely dark visual field believes that the light moves from its fixed position. This “self-motion” (auto-kinetic) is caused, in part, by the nearly imperceptible movements of the eye known as saccades. Ordinarily the visual system compensates for these naturally occurring motions of the eye, but when only a single light is visible with no frame of reference, the light appears to wander in unpredictable directions and at variable speeds. This illusion was first noted by astronomers when viewing a single star on a very dark night.

Muzafer Sherif made use of the autokinetic effect in his 1936 studies of the development of social norms. Norms provide individuals with frames of reference that guide their thoughts, emotions, and actions in social situ-
Automobile Industry

The turn of the twentieth century witnessed the dawning of the automobile industry. Tinkering by bicycle, motorcycle, buggy, and machinery entrepreneurs in Europe and the United States led to the first prototypes of automobiles in the late nineteenth century. French woodworking machinery makers Rene Panhard and Emile Levasseur built their first car in 1890 with an engine designed in Germany by Gottlieb Daimler and Wilhelm Maybach. Armand Peugeot, a French bicycle maker, licensed the same engine and sold his first four lightweight cars in 1891. German machinist Carl Benz followed the next year with his four-wheeled car and in 1893 Charles and Frank Duryea built the first gasoline-powered car in the United States. Ransom Olds is credited as the first mass producer of gasoline-powered automobiles in the United States, making 425 “Curved Dash Olds” in 1901. The first gasoline-powered Japanese car was made in 1907 by Komanosuke Uchiyama, but it was not until 1914 that Mitsubishi mass-produced cars in Japan.

Each region in the triad—North America, Europe, and Asia—has made significant contributions to process, product, and organization throughout the twentieth century. These innovations together have shaped the competitive structure of the automotive industry that exists today. The organization of production inputs—such as labor and suppliers of components and materials—as well as the configuration of distribution channels are also important dimensions of the growth and evolution of the industry. Furthermore, various forces outside the industry shape industry structure and strategies: trade flows; regional and international movement of capital; regional and global policies on trade, environmental regulation, and intellectual property, particularly in emerging economies; and the infusion of information technology throughout the procurement, production, and distribution systems.

The automotive industry is dynamic and vast, accounting for approximately one in ten jobs in industrialized countries. Developing countries often look to their local automotive sector for economic growth opportunities, particularly because of the vast linkages that the auto industry has to other sectors of their economy.

The turn of the twentieth century witnessed the dawning of the automobile industry. Tinkering by bicycle, motorcycle, buggy, and machinery entrepreneurs in Europe and the United States led to the first prototypes of automobiles in the late nineteenth century. French woodworking machinery makers Rene Panhard and Emile Levasseur built their first car in 1890 with an engine designed in Germany by Gottlieb Daimler and Wilhelm Maybach. Armand Peugeot, a French bicycle maker, licensed the same engine and sold his first four lightweight cars in 1891. German machinist Carl Benz followed the next year with his four-wheeled car and in 1893 Charles and Frank Duryea built the first gasoline-powered car in the United States. Ransom Olds is credited as the first mass producer of gasoline-powered automobiles in the United States, making 425 “Curved Dash Olds” in 1901. The first gasoline-powered Japanese car was made in 1907 by Komanosuke Uchiyama, but it was not until 1914 that Mitsubishi mass-produced cars in Japan.

Each region in the triad—North America, Europe, and Asia—has made significant contributions to process, product, and organization throughout the twentieth century. These innovations together have shaped the competitive structure of the automotive industry that exists today. The organization of production inputs—such as labor and suppliers of components and materials—as well as the configuration of distribution channels are also important dimensions of the growth and evolution of the industry. Furthermore, various forces outside the industry shape industry structure and strategies: trade flows; regional and international movement of capital; regional and global policies on trade, environmental regulation, and intellectual property, particularly in emerging economies; and the infusion of information technology throughout the procurement, production, and distribution systems.

The automotive industry is dynamic and vast, accounting for approximately one in ten jobs in industrialized countries. Developing countries often look to their local automotive sector for economic growth opportunities, particularly because of the vast linkages that the auto industry has to other sectors of their economy.
lean production (1973–present), which was initially developed at Toyota under the leadership of Taichi Ohno during the 1950s, and which introduced a revolutionary management process of product-development and production.

Mechanization of auto production has also been transformed over the past century, led by the need for faster and lower-cost production on the supply side of the industry. Ford’s mass-production system relied on standardized designs to enable the construction of assembly plants that were fully automated and utilized interchangeable auto parts. In its heyday, between 1908 and 1920, Ford streamlined the assembly process to the point where it took just over an hour and a half to produce one car. Setting the industry standard for production enabled Ford to take the lead in market share, but it also led to a complacent mindset that hindered innovation. In the 1920s General Motors improved on Ford’s assembly line process by introducing flexibility into the production system, enabling faster changeovers from one model to the next. However, it took half a century after Ford stopped mass producing Model T’s in 1927 for another production paradigm to emerge as the standard in the global automotive industry. Toyota’s lean production system—which had its beginnings in 1953—drove productivity to new heights by replacing the “push” system with a “pull” system. Instead of producing mass quantities of vehicles and pushing them through to dealerships to sell to customers or hold as inventories, the lean system pulled vehicles through the production process based on immediate demand, minimizing inventories at suppliers, assemblers, and dealerships. Just-in-time production also gave a larger responsibility for product design, quality, and delivery to assembly workers and suppliers than did the mass-production system. Suppliers were not vertically integrated into auto assembler operations, but rather networked to the assemblers via long-term contracts. This total system of cost-minimization and responsiveness to customer demands revolutionized auto manufacturing on a global scale, although the model has been adapted to regional conditions.

Product innovation in the automotive industry has mainly been a response to customer demands, although product positioning is a critical strategic variable for automakers. Ever since General Motors began producing different types of vehicles for different product segments, thereby ending the reign of Ford’s low-price, monochromatic Model T, the ability to vary products on several dimensions has been the main strategic variable of auto producers. U.S. automakers have mainly been responsive to customers’ desires for comfort, speed, and safety, and have developed rugged drive trains, plush suspensions and interiors, and stylish chassis and bodies. In contrast, European auto producers have focused their attentions on performance and agility features of vehicles, such as steel-belted radial tires, disc brakes, fuel injection, and turbo diesel engines. For Japanese producers, the miniaturization culture and the scarcity of fuel, materials, and space largely determine the specifications of cars.

Organizational innovations have also occurred over the past century. In concert with the introduction of mass production techniques came the vertical organization of production processes. Auto assemblers internalized the production of critical components in an effort to minimize transaction costs associated with late deliveries and products that were not produced to exact specifications. For example, the share of components purchased from outside suppliers relative to the wholesale price of an American car dropped from 55 percent in 1922 to 26 percent in 1926. During the Great Depression, this propensity to internalize production eased, with suppliers gaining independence and importance in the replacement parts market. Automakers found that a highly vertical organizational structure did not permit the flexibility in operations necessary for product innovation. In the 1930s, Ford’s vertically integrated and centrally controlled organizational structure gave way to the multidivisional organizational structure that was implemented by Alfred Sloan at General Motors Corporation (GM). Sloan’s decentralized configuration of GM fostered an independent environment for the development, production, and sales of a wide variety of vehicles. With the lean production revolution came the introduction of organizational reform referred to as the extended enterprise system. Although Japanese auto manufacturers established and diffused efficient mechanisms of supply chain management throughout the industry, Chrysler Corporation is credited with successfully implementing these innovations in the American venue.

**COMPETITIVE STRUCTURE**

Rivalry among assemblers in the automotive industry, once contained within national boundaries, has evolved into global competition. First movers established market dominance in the early 1900s, and their brands are still the most recognized by consumers today. The fact that auto producers choose market strategies based on what their rivals are doing indicates that this is an oligopolistic industry. What is interesting here is that market leadership remains dynamic: It is not a given that General Motors or Toyota or DaimlerChrysler will be the market leader of tomorrow.

Before industry standards for products and production were established, hundreds of automakers existed, each vying to establish a beachhead in the industry. In the United States, for example, the year 1909 saw the largest number of automakers in operation in a given year—272 companies. It is estimated that in the first twenty years of
the industry's existence, over five hundred firms entered
the industry in the United States alone. The 1920s
brought a wave of precipitous exits by auto manufactur-
ers, with many firms merging into more profitable com-
panies. In the 1930s General Motors became the market
leader, with Ford slipping to second place because of a
yearlong changeover in production from the Model T to
the Model A. By 1937 General Motors, Ford, and
Chrysler—long referred to as the Big Three—had 90 per-
cent of total sales in the U.S. market, forming a domi-
ant-firm oligopoly (General Motors accounted for
44.8%, Chrysler 25%, and Ford 20.5%). By the 1960s,
only seven domestic auto producers remained.

In the late 1990s Japanese auto manufacturers took
over more than a quarter of the U.S. market, and Big
Three market share slipped below 70 percent. Today, there
are only two-and-a-half U.S. automakers—General
Motors, Ford, and DaimlerChrysler—collectively captur-
ing 58.7 percent of the U.S. market. GM still has the
largest share of the U.S. market (27.3%), but Toyota's
market share in the United States is just one percentage
point below Chrysler's (13%). Worldwide, market con-
centration has also been declining since the mid-1980s,
with entrants such as Hyundai/Kia diluting the collective
market share held by dominant automakers.

Market rivalry in the auto industry centers on two
strategic variables: (1) product variety and quality, and (2)
transactions price, which is manipulated to boost sales.
The tension between shareholder concerns about short-
term profitability and a company’s desire for long-term
viability is palpable. Automakers must attract and main-
tain a solid customer base, building allegiance to brand
name in an effort to maximize earnings in the long term.
Maintaining high customer repurchase rates is critical to
long-term profitability in the industry. Therefore,
automakers attempt to attract and keep customers from
the purchase of their first car in their late teens until retire-
ment and thereafter. Product variety at all of the major
automakers spans the full spectrum from small to full-
sized cars, although some automakers are better known in
particular market niches. For example, Mercedes, BMW,
Lexus, Infiniti, and Acura capture a third of the upscale
market in the United States, whereas Buick, Ford,
Mercury, and Toyota are known for their family-styled tra-
ditional cars. Turnkey reliability is the hallmark of
Japanese makes, whereas Ford, Chevrolet, and Toyota
appeal to buyers of small or sporty vehicles. The fastest
growing market segment in the United States in recent
years has been sport utility vehicles (SUVs). By the early
2000s, SUVs captured 55 percent of vehicle sales.

Auto producers have used various means to develop a
full line of product offerings for a broad spectrum of cus-
tomers. For example, GM has historically used acquisition
or shareholdings to offer a variety of brands—including
Chevrolet, Oldsmobile, Pontiac, Buick, GMC, and
Cadillac. In the late 1970s, GM purchased shares in
Suzuki and Isuzu compacts and imported those vehi-
cles, in part to satisfy Corporate Average Fuel Efficiency
requirements. In recent years, Ford-Mercury-Lincoln has
also diversified its portfolio by acquiring Volvo and Jaguar.
Toyota, Honda, and Nissan initiated a clever marketing
ploy in the 1980s aimed at selling luxury vehicles in the
United States: They named their luxury brands Lexus, Acura,
and Infiniti, respectively, even though these cars
are built on the same platforms as their other vehicles.

Product quality has been converging over time. As
recently as 1998, European and Japanese makes had fewer
vehicle defects than average for cars in their first few
months on the road, whereas U.S. and Korean cars had
more defects than average. By 2004 vehicles from all four
regions were within ten defects per hundred vehicles of
the average, which had fallen from 176 to 119 defects per
hundred vehicles. Interestingly, both the Japanese and the
South Korean newcomers outperformed U.S. and
European vehicles on this quality scale.

To attract customers to a brand, small cars are at
times used as a loss leader; that is, a firm will sell their low-
end vehicle at a price below invoice, while recuperating
large returns on SUVs, luxury brands, and specialty cars.
Another pricing strategy that is often used by automakers
to clear inventories and to get the customer in the door is
discounting. At particular times of the model year (which
typically begins in October and ends in September of the
following year) direct assembler-to-customer discounts as
well as dealer-to-customer discounts are used to adjust
transaction prices to ebbs and flows in demand. If the rev-
olutionary pull system becomes pervasive in the auto
industry, the need to manage inventories through end-of-
model-year discounting could become obsolete. However,
product positioning will continue to be an important
competitive variable for automakers because demographic
attributes drive the needs and desires of customers.

Automotive suppliers have been gaining global
importance in the automotive industry, taking on the pri-
mary responsibility for product development, engineer-
ing, and manufacturing for some critical systems in the
automobile. In its initial stage of development, the auto
industry was comprised of auto assemblers that integrated
parts production into the enterprise. Independent auto
parts producers mainly supplied aftermarket parts.
Throughout the twentieth century, this vertically inte-
grated structure within assemblers has been replaced by a
more network-oriented tiering structure. Here, assemblers
coordinate design and production efforts with premier
first-tier suppliers, while these suppliers are responsible for
global coordination of the supply of their subassemblies

and for the coordination of production by sub-tier parts manufacturers. Thus, first-tier suppliers have been rivaling automakers in market power and in share of value added to any given vehicle. While it seems unlikely at this time that such suppliers will evolve into complete vehicle manufacturers, the profit generated by the sale of a vehicle is shifting toward the supplier and away from the traditional assembler. Automakers, therefore, face stiff rivalry both from other automakers and from dominant suppliers. Only a select few suppliers have achieved “true global competency” in the production of automotive systems, but the industry trend is pointing in this direction. The “Intel Inside” phenomenon seen with computers—in which the supplier’s brand identity is critical for the sale of the final product—has not yet taken over the automotive industry, although “Hemi Inside” could be an emerging example.

As manufacturing momentum shifted toward auto parts suppliers, so too did the share of labor. Since the early 1960s, total employment in the U.S. auto industry has ranged between 700,000 and just over 1 million workers. Up until the mid-1980s, auto assemblers employed the majority of those workers, but from then on the employment share for automotive parts suppliers in the United States has consistently been greater than the share of workers at assembly plants. Between 1987 and 2002, the share of automotive sector employment at assembly plants declined from 44 percent to 36 percent, whereas the share of workers at automotive suppliers increased from 46 percent to 54 percent. Add to this change the influx of mostly non-unionized automotive transplants (foreign suppliers and assemblers), the outsourcing of parts and assembly to foreign nations, and the general sectoral shift away from manufacturing toward the service sector, and it is clear that the 1980s marked a turning point for labor in the U.S. auto industry.

Labor unions that represent autoworkers in the United States have had to weather a myriad of undulations in domestic business cycles since 1935, when the United Auto Workers (UAW) was founded. (Other unions that represent auto workers in the United States include the International Association of Machinists and Aerospace Workers of America, the United Steelworkers of America, and the International Brotherhood of Electrical Workers.) Recent changes in the organization of the auto industry and in the ownership of domestic firms, however, present uniquely formidable challenges to union strength. First, the implementation of lean manufacturing techniques and the drive to achieve globally competitive prices, quality, and delivery standards is likely to precipitate job cuts as suppliers strive to increase productivity. Second, only a few automotive transplants in the United States allow union status—namely, NUMMI (GM-Toyota), Diamond Star (Chrysler-Mitsubishi), and Auto Alliance (Ford-Mazda), all of which are joint ventures with U.S. companies. Yet, total transplant employment is rising. Between 1993 and 2003 employment at transplants in the United States rose from 58,840 to 93,408. The UAW continues to strive to organize labor at transplants and is targeting supplier parks near unionized assemblers in an attempt to maintain locational control. Third, outsourcing of production in a continuously globalizing industry diminishes the bargaining power of unions not just in the United States, but in Europe as well. Fourth, auto assemblers and suppliers are increasing their utilization of temporary workers. In Germany, BMW has a pool of temporary workers that can be utilized at different factories as needed, and in the United States auto assemblers are increasingly employing contract workers to reduce costs.

The globalization of the auto industry appears to challenge the status quo for labor in traditional regions of vehicle production. As employment in the industry shifts toward the supplier sector and toward emerging economies, the attempt to maintain good wages at traditional plants is paramount for autoworkers. Total hourly labor cost at GM and Ford for 2005 was estimated at $65.90, with $35.36 in wages and $30.54 in benefits, healthcare, and retirement costs. Other estimates for 2004 show earnings of production workers at assembly plants at $1,217 per week, whereas workers at parts plants earn $872 weekly, and workers in all manufacturing industries make an average of $529 per week. Autoworkers—particularly those who work in assembly plants in developed countries—certainly have a great deal at stake as the industry continues to globalize.

By contrast to labor, the power that dealerships exert on assemblers has historically been minimal. The push system of production meant that dealerships were the repositories for the inventory overruns of auto assemblers. Also, up until the 1960s, dealerships could legally be controlled by automakers. Therefore, auto dealers earn the majority of their profits from aftermarket sales of parts, accessories, supplies, and service, all of which are a small portion of their business. With the movement toward a pull system of production, dealerships could play a more important role in the automotive industry. However, the countervailing threat to dealerships is Internet-based sales, an innovation that stands to mitigate the market power of dealerships vis-à-vis auto assemblers.

MAJOR COUNTRIES OF PRODUCTION AND CONSUMPTION
The Worldwide Big Three automakers are General Motors, Toyota Motor Corporation, and Ford Motor Company. In 2004 these companies had worldwide mar-
ket shares of 13 percent, 11 percent, and 10 percent, respectively, and production shares that closely mirrored these numbers. Interestingly, the geocenter of automotive production is the Asia-Pacific region, with over 23 million units produced in 2004. Japan was the dominant producer, with China a distant second at half of Japan’s output that year. Western Europe and North America ranked a distant second and third in worldwide production, respectively, producing between 16 and 17 million vehicles in 2004. Germany is the dominant producer in western Europe, while the United States produces the lion’s share of vehicles in North America.

The biggest consumers of vehicles are North Americans, with Asian Pacific and western European customers a close second and third. Although per-capita ownership of vehicles in China is very small (1.5 vehicles per 100 households compared to 50 vehicles per 100 households in Japan in 2001), the number of vehicles sold in China in 2004 fell only a few hundred thousand short of vehicle sales in Japan. In addition, the growth rate of sales in Japan between 2003 and 2004 was a sparse 0.1 percent, whereas China experienced a 17.2 percent growth in vehicle sales during that period. The other countries with over a million in vehicle sales per year that also had double-digit growth in vehicle sales in 2004 were Russia (24 percent), India (18.2%), Brazil (17%), Mexico (11.8%), and Spain (10.2%). Market opportunities in these countries are highly dependent on macroeconomic performance and policies. Hence, automakers pursue a portfolio approach to production and marketing, given the fragility of economic growth in these regions.

Since the 1960s, auto analysts have looked to a few regions for sources of new productive capacity: Eastern Europe, Latin America, India, and China. By 1980, however, the eastern European motor industry had stagnated and during the 1980s severe economic and political turmoil caused halting growth in the Latin American automotive sectors. In the 1990s liberalization of trade and investment policies gradually emerged in India and China. Today, China has captured attention as the location for new automotive productive capacity. Beginning with Volkswagen’s investment in 1985, all of the major automakers have established productive capacity in China through joint-venture relationships with local automakers.

In the mid 1970s passenger car production was practically nonexistent in China. Thirty years later, sales and profit rates had soared, although capacity utilization is low (between 50% and 60%) and inventories are high relative to their Japanese, European, and U.S. competitors. If China continues on its pathway from centrally planned economy to modest marketization, and continues to become more fully integrated into the global economy, then its domestic automotive industry will most likely steadily expand.

**IMPORTANCE OF THE INDUSTRY**

**FOR MACROECONOMIC ACTIVITY AND INTERNATIONAL TRADE**

The automotive industry is an important sector of the overall economy, particularly in industrialized countries. For example, the automobile is second only to a house in purchase value for the average American household. The average manufacturing job in the automotive sector pays 60 percent more than the average U.S. job. It is estimated that the industry generates 10.4 jobs for every worker directly employed in automotive manufacturing and support services (excluding auto dealers) in the United States. Employment spillovers are seen in manufacturing and nonmanufacturing industries, including retail trade and services. In 2000 motor vehicles and equipment (assemblers and suppliers) expenditures on research and development (R&D) outpaced R&D spending in many of the thirty-nine largest industry groups, including pharmaceuticals and medicines, semiconductors and other electronic components, communications equipment, and computers and peripheral equipment.

Motor vehicles are also a major component of international trade and foreign direct investment between countries. In 2000 the share of automotive products in world trade was 9.4 percent, unchanged from its share a decade earlier. Western Europe, North America, and Asia in declining order are the global leaders in exports and imports. While western Europe and Asia are net exporters of vehicles, North American imports far outpace exports. In North America, exports have remained relatively flat since the 1980s, whereas imports have ratcheted up. North America, eastern Europe, the Middle East, and Africa are all net importers of automotive products. Intraregional trade figures show that intra–western European trade was the largest in value at almost US$200 billion that year, intra–North American trade was second at US$87.7 billion, and intra-Asian trade was the lowest at US$19.6 billion. Interestingly, intra–North American trade declined by 10 percent compared to 1990. The fastest growing region-to-region trade was North America’s trade with its European and Latin American partners.

From time to time barriers have been erected around the globe to protect local automotive sectors. For example, over the past twenty years, countries in North America and Europe have erected tariff and non-tariff barriers specifically applied to trade in automobiles. Between 1981 and 1988, the United States and Japan “voluntarily” agreed on a fixed number of vehicle units that Japan would export to the United States.
and Japan also entered a voluntary export agreement (VER) between 1990 and 1999, as Japanese imports to Europe began to surge. In both cases, the VERs were partly responsible for an increase in transplant production, as Japanese auto producers jumped over the trade barriers to erect manufacturing plants in the United States and Europe. Although the transplants have become a critical component of the local manufacturing landscape, the jobs and exports that they generate are weighted against their dampening effect on wages and the costs that some local governments incur to attract foreign firms to their region.

In developing countries, trade and investment restrictions in the automotive sector take the form of local content rules, tariffs, and quotas. The impetus behind these protectionist measures is to give local producers a chance to develop before they face competition from world-class auto producers that are more productive and therefore have lower unit costs. In recent decades, regional trade pacts have been implemented that liberalize many of these local content, investment, and trade restrictions. The North American Free Trade Agreement (NAFTA), which was implemented in 1994, is one significant example. When the United States and Canada included Mexico in their free trade pact on trade in automobiles and parts, Mexico reduced tariffs for its northern partners and lifted restrictions on local investment for all foreign companies, allowing domestic status for transplant operations.

One of the critical determinants of the location of assembly plants and their related suppliers is production cost. Production costs and market opportunities are the primary reasons why jobs are shifting away from the traditional geographic centers of vehicle production. At the same time, implementation of the lean production paradigm is shifting the operational center of vehicle production toward first-tier suppliers with global capabilities. Variable costs of production—costs that depend on the number of vehicles produced—include expenditures on materials and labor. In the automotive industry, material costs range between 22 and 50 percent, whereas labor costs range from 10 to 20 percent. Because these costs vary by region and product produced, auto assemblers and suppliers are actively engaged in assessments and adjustment processes that lead to changes in the configuration and operations of their plants. Yet, the evolution of North American, European, Asian, and South American trading blocs has significant implications for the geographic configuration of production and trade flows. While it remains an important factor, comparative advantage is not the sole determinant of trade patterns in the automotive industry.

CHANGES AND CHALLENGES IN THE AUTOMOBILE INDUSTRY

Auto industry analysts anticipate major organizational and geographical changes in the global auto industry in response to innovations in auto-manufacturing techniques, reconfigurations in the loci of demand for vehicles, and growing environmental concerns. A new model of labor utilization will develop as suppliers and automakers adjust to flexible manufacturing practices and the globalization of their operations.

As of 2007, overcapacity in the global automotive industry is estimated at 20 million units, which is approximately one-third of global annual production or the productive capacity of the western European automakers. With minimum efficient scale of production at an assembly plant estimated at 200,000 vehicles, dozens of assembly plants are likely to close as automakers strive to improve their profitability. Capacity unitization of about 75 percent is the tipping point below which automakers are in jeopardy of experiencing financial losses.

Overcapacity, therefore, has triggered mergers, acquisitions, and network alliances. Auto companies are consolidating and simplifying control and development functions, and attempting to minimize new investment initiatives, the number of unique parts in their vehicles, the number of design and production tools used, the number of components made in-house, and the number of direct supplier relationships. Assemblers are also utilizing modularization to simplify final assembly processes, and they are experimenting with various organizational designs as part of the restructuring process. Automakers and parts suppliers are utilizing vertical and horizontal strategic alliances with the expectation that they will facilitate the development of new products and the spread of automotive productive capacity to new geographic regions. These ventures, however, will also create new competitors, particularly in emerging economies.

However, consolidation has not proven to be a panacea for optimizing productive capacity in the industry. Mergers have typically occurred between companies that have complementary product lines and therefore the opportunities for retiring some plants are diminished. Effective rationalization brings job losses. Yet mergers between companies from different countries (such as Germany's Daimler-Benz and Chrysler in the United States) have not typically brought capacity reduction, because political forces strive to maintain domestic jobs.

Analysts anticipate that production will shift away from traditional regions in North America, Europe, and East Asia to Brazil, China, India, and countries in Southeast Asia. Trade liberalization will facilitate this geographical shift in production, as well as increased commodilization—the sharing of principal components and
platforms—although consumer tastes will militate against the full introduction of a homogeneous “world car” from each automaker. Commonization—coupled with the differentiation of products based on regional tastes—is already practiced by Ford and Honda, and other automakers are also adopting this practice. There is no clear evidence, however, that automakers are converging on one comprehensive paradigm of production.

Economic growth in East and South Asia is also expected to influence the locational decisions of auto producers. For example, economic and political developments in China during the past decade have had considerable influences on global sourcing and production decisions of German, American, and Japanese automakers. Growing disposable income among middle- and upper-income citizens, burgeoning industrial development in coastal regions, and the periodic liberalization of personal finance markets are driving demand for passenger cars and commercial vehicles in China. Given these trends and the size of the market, automakers anticipate good returns from their productive capacity in the Far East. Yet, exuberance over the potentially hot auto market in China is tamed from time to time by the prospect that the underpinnings of that market rests importantly on government fiat.

The automobile industry will also need to continue to address a range of environmental concerns related to carbon dioxide levels and other health risks. While estimates vary widely as to the impact that vehicle emissions have on the global environment, automakers have made emissions and safety adjustments to their automobiles over time. In the United States, rules and guidelines that originated in the 1970s—such as the Corporate Average Fuel Efficiency Standards (CAFE) and federal safety regulations—have brought about significant emission reductions. Thirty years since CAFE standards were put in place, new cars in the United States emit approximately 1 percent of the smog-producing compounds emitted by new cars in the 1970s. This progress is not solely the result of government regulations, however. The Alliance of Automobile Manufacturers—a trade association of nine automakers from the United States, Germany, and Japan—has identified clean energy technologies as a means to further economic growth in the industry. It is important to note, however, that increased use of vehicles and persistent use of vehicles with old technology mitigate some of these important strides.

Automakers around the globe are also engaged in developing new technologies and products, such as electronic fuel cells, navigational systems that manage congestion problems, and “telematics” (telecommunications capabilities). Information technology networks will be fully integrated into the R&D, procurement, manufacturing, and distribution functions of the enterprise structure. The Internet and Web-based communications are expected to drive the next transformation in the automobile industry. The next frontier in distribution channels is fully to implement a build-to-order system. While dealerships might not become obsolete, the efficiency of the pull system will reduce their inventories and associated costs. Implementing a system similar to the Dell Direct model could mean significant cost reductions in the distribution and purchasing functions of firms in the industry.

AUTONOMY

Since the Enlightenment, the concept of autonomy has implied the capacity for self-regulation, and as a corollary of this capacity, the right to self-determination. Although many early thinkers from both the East and the West espoused the idea of self-regulation in some form, including Tertullian (second and third centuries), Thomas Aquinas (thirteenth century) and the Chinese philosopher Lao-tzu (sixth century BCE), it is generally associated with the development of Kantian philosophy and with the liberalism of the English philosophers John Stuart Mill (1806–1873) and John Locke (1632–1704), as well as the Scottish economist Adam Smith (1723–1790).

The most significant figure in the development of autonomy as a grounding concept of moral philosophy is undoubtedly Immanuel Kant (1724–1804), whose critical philosophy rests on the presumption that all human beings are rational beings and that reason is defined by the capacity for self-regulation. Reason, in Kant's analysis, is a faculty that permits individuals to subject themselves to law, not merely because it is their desire to do so, but because moral law, as the product of reason rather than empirical deduction, has a quality of necessity that is independent of any question of ends and, hence, of the desires felt by individual subjects. A crucial aspect of Kant's moral philosophy, one that was later developed by Karl Marx (1818–1883), was the notion that reason and desire could be opposed to one another, and indeed, that the autonomy of moral law implies the independence of reason from desire.

Like Jean-Jacques Rousseau (1712–1778), who influenced him greatly, Kant felt that the implications of moral autonomy extended to the political realm: The development of individual capacities for self-regulation required freedom from restraint by those forces that might otherwise cultivate desire against reason. Accordingly, he is often
interpreted as an advocate of limited government—though his conception of what constituted limited government should not be confused with that of the political liberals following Mill and Locke, or the Smithian economists.

Mill in particular shared with Kant a sense that the opposite of moral autonomy is “servile dependence.” Significantly, then, it was not society per se so much as the hierarchy of obligation and indebtedness that threatened the autonomy of the individual and his or her capacity to make free judgments. In the political realm, Mill’s theory implied that individuals exercise their freedoms in relation to other individuals, and it is this cooperation that provides the means by which consensual governments are constituted.

It fell to Adam Smith to explicate the processes by which individual freedom and the complex organization of society could be accommodated and sustained independently of any legislative authority. He theorized a natural tendency to “truck, barter, and exchange” as the ground of those processes by which the division of labor develops naturally. In the forms of economic liberalism that owe their debt to Smith, the idea of autonomy was thus closely linked to one of spontaneous self-order. And it was used to legitimate arguments against governmental intervention in markets and other forms of economic life.

Kant was never fully able to extend the formalism of his own argument to all persons (he withheld the faculty of reason from Africans and aboriginals, and he doubted the capacities of women or servants to exercise free judgment). Moreover, the formalism that was intrinsic to his argument also encouraged a conflation between the presumption of a universal faculty (reason) and the universal equality of all to exercise this faculty of judgment in the actual social sphere. Smith’s argument, like that of the liberal political economists who followed him, presumed that government exercises a more coercive and inhibiting influence on individuals than do other social forces, such as capital or organized labor. This presumption—that only states (through their legislative bodies) interfere with individual autonomy—has been one of the major objects of critique within radical political philosophy, from Marx forward. The crux of such critique has been a recognition of the complex social determinants of the very consciousness within which reason appears as a faculty, and a value as such. Even within liberal traditions, there is disagreement as to whether individual autonomy is better served by a government that regulates capital and other social institutions, or by one that allows corporations (including not only economic but also religious institutions) to be considered as individuals, and hence as entities whose regulation would constitute a violation of their rights.

Politically, the concept of autonomy no longer applies exclusively to the relationship between individuals and social institutions; it also describes the status of recognized minority communities within larger social contexts, and particularly state formations. In this case, autonomy is closely linked to the idea of a collective right to self-determination, and as such is provided for by the United Nations under the terms of the International Covenant on Economic, Social, and Cultural Rights (adopted in 1966 and entered into force in 1976). This covenant not only provides for a right to self-determination, but also recognizes the right of “all peoples to freely dispose of their natural wealth and resources.” However, just as liberal theory is conflicted in its assertion of the rights of individuals while it insists that these rights cease to exist when they intrude upon the rights of another individual, the rights of “peoples” may conflict with the perceived prerogatives of states. This is especially likely when such states comprise several distinct ethnolinguistic communities, and when one or another community dominates numerically, economically, or historically through the exercise of force. The structure by which states “grant” autonomy to regions within their territorial jurisdiction expresses the ambivalence of this concept of autonomy.

SEE Autoregressive Models.

AUTOREGRESSIVE MODELS

The statistical analysis of “time series” data, which are common in the social sciences, relies fundamentally on the concept of a stochastic process—a process that, in theory, generates a sequence of random variables over time. An autoregressive model (or autoregression) is a statistical model that characterizes or represents such a process. This article provides a brief overview of the nature of autoregressive models.

BACKGROUND

In the discussion to follow, I will use the symbol $y_t$ to represent a variable of interest that varies over time, and that can therefore be imagined as having been generated by a stochastic process. For example, $y_t$ might stand for the value of the gross domestic product (GDP) in the United States during a particular year $t$. The sequence of the observed values of GDP over a range for $t$ (say, 1946 to 2006) is the realization, or sample, generated from the process $y_t$. One can imagine that, before they are known or observed, these values are drawn from a probability distribution that determines the likelihood that $y$ takes on particular numerical values at any point in time. Time-series analysis is the set of techniques used to make inferences about this probability distribution, given a realization from the process. A key aspect of time series, especially when compared to cross-sectional data, is that for most time series of interest, probable values at a particular point in time depend on past values. For example, observing a larger than average of GDP in one year typically means observing a larger than average value for GDP in the following year. This time, or serial, dependence implies that the sequential order of a stochastic process matters. Such an ordering, however, is usually not important for observations on, say, individual households at a point in time because this ordering is arbitrary and uninformative.

A general way to characterize a stochastic process is to compute its moments—its means, variances, covariances, and so on. For the scalar process above, these moments might be described as:

\[ E(y_t) = \mu \]
\[ E(y_t - \mu)(y_{t-k} - \mu) = \nu_k. \]

Equation 1 defines the (unconditional) mean of the process, while equation 2 defines the (unconditional) covariance structure—the variance for $k = 0$, and the autocovariances for $k > 0$. (Some distributions, such as the well-known normal distribution that takes on the shape of a “bell-curve,” are fully characterized by means and covariances; others require specification of higher-order moments.) Autocovariances measure the serial dependence of the process. If $\nu_k = 0$ for all $k \neq 0$, then the process is serially uncorrelated, which implies that past values of the process provide no information that will help predict future values. Such a process is called white noise.

The moments in equations 1 and 2 are quite general, but they are often difficult to estimate and use in practice. Time-series models, on the other hand, impose restrictions on this general structure in order to facilitate estimation, inference, and forecasting. Typically, these models focus on conditional probability distributions and their moments, as opposed to the unconditional moments in equations 1 and 2 above.

AUTOREGRESSIVE MODELS

An autoregression (AR) is a model that breaks down the stochastic process $y_t$ into two parts: the conditional mean as a linear function of past values (to account for serial dependence), and a mean-zero random error that allows for unpredictable deviations from what is expected (given the past). Such a model can be expressed as:

\[ y_t = a_0 + a_1 y_{t-1} + \cdots + a_p y_{t-p} + e_t \]

Here, $a_0$ is a constant, $a_1$ through $a_p$ are parameters that measure the specific dependence of $y$ on its past (or lagged) values, $p$ is the number of past values of $y$ needed to account for the serial dependence in the conditional mean (the lag order of the model), and $e_t$ is a white-noise process with variance $E e_t^2 = \sigma^2$. The value $e$ is interpreted as the error in forecasting the current value of $y$ based solely on a linear combination of its past realization. The lag order $p$ can take on any positive integer value, and in principle it can approach infinity. Because $y_{t-1}$ depends only on random errors dated $t-1$ and earlier, and because $e_t$ is serially uncorrelated, $e_t$ and $y_{t-k}$ must be uncorrelated for all $t$ and whenever $k$ exceeds zero.

Equation 3 is a $p^{th}$ order autoregressive model, or AR($p$), of the stochastic process $y_t$. It is a complete representation of the joint probability distribution assumed to generate the random variable $y$ at each time $t$. These models originated in the 1920s in the work of Udny Yule,
Eugen Slutsky, and others. The first known application of autoregressions was that of Yule in his 1927 analysis of the time-series behavior of sunspots (Klein 1997, p. 261). An autoregression explicitly models the conditional mean of the process. Because the mean of the error term $\varepsilon$ is zero, the expected value of $y_t$, conditional on its past, is determined from equation 3 as:

$$E(y_t \mid y_{t-1}, y_{t-2}, \cdots) = a_0 + a_1 y_{t-1} + \cdots + a_p y_{t-p} \quad (4)$$

There is, however, a unique correspondence from the unconditional moments in equations 1 and 2 to the parameters in the AR model. This correspondence is most easily seen for the AR(1) process (i.e. $p = 1$, so that only the value of the process last period is needed to capture its serial dependence). For the AR(1) model, the unconditional mean and covariance structure are, respectively,

$$\mu = \frac{a_0}{1 - a_1} \quad (5)$$

$$\nu_k = a_k \left( \frac{\sigma^2}{1 - a_1^2} \right) \text{ for all } k. \quad (6)$$

This correspondence clarifies how the AR model restricts the general probability distribution of the process. (Note that a large number of unconditional moments can be concisely represented by the three parameters in the model, $a_0$, $a_1$, and $\sigma^2$.)

**Stationarity and Moving Averages**

A stationary stochastic process is one for which the probability distribution that generates the observations does not depend on time. More precisely, the unconditional means and covariances in equations 1 and 2 are finite and independent of time. (Technically, these conditions describe covariance stationarity; a more general form of stationarity requires all moments, not just the first two, to be independent of time.) For example, if GDP is a stationary process, its unconditional mean in year 2006 is the same as its mean in, say, 1996, or any other year. Likewise, the autocovariance between GDP in 2006 and 2005 (one year apart) is the same as the autocovariance between GDP in 1996 and 1995 (one year apart), or any other pair of years one year apart. Stationarity is an important condition that allows many of the standard tools of statistical analysis to be applied to time series, and that motivates the existence and estimation of a broad class of linear time series models, as will be seen below.

Stationarity imposes restrictions on the parameters of autoregressions. For convenience, consider once again the AR(1) model. A necessary condition for the AR(1) process $y_t$ to be stationary is that the root ($z$) of the following equation be greater than one in absolute value:

$$1 + a_1 z = 0. \quad (7)$$

Since the root of equation 7 is $1/a_1$, this condition is identical to the condition $|a_1| < 1$. The proof of such an assertion lies beyond the scope of this article, but equation 6 shows, heuristically, why the condition makes sense. From this equation, we can see that if $a_1 = 1$, then the variance of the process approaches infinity; if $a_1$ exceeds 1 in absolute value, then the variance is negative. Neither of these conditions is compatible with a stationary process. The general condition for the stationarity of the AR(p) model is that the $p$ roots of the following equation be greater than one in absolute value (Hamilton 1994, p. 58):

$$1 - a_1 z - a_2 z^2 - \cdots - a_p z^p = 0. \quad (8)$$

For an autoregressive process of any order that satisfies this condition, the $q^{th}$ order moving average (MA) representation of the process can be written as:

$$y_t = \mu + \varepsilon_t + c_1 \varepsilon_{t-1} + c_2 \varepsilon_{t-2} + \cdots + c_p \varepsilon_{t-p}. \quad (9)$$

Here, $\varepsilon_t$ is the white-noise forecast error, and the parameters $c_1, c_2, \ldots, c_p$ approach 0 as $k$ gets large. For example, using the tools of difference equation analysis, we can show that, for the AR(1) model, $c_1 = a_1$, $c_2 = a_1^2$, $c_3 = a_1^4$, and so on. Clearly, the limit of $a_1^k$ as $k$ gets large is zero given the stationarity condition above. The correspondence between the MA coefficients and the autoregressive coefficients in the more general AR(p) case is more complex than for the first-order case, but it can be obtained from the following iteration, for values of $k$ that exceed 1 (Hamilton 1994, p. 260):

$$c_k = a_1 c_{k-1} + a_2 c_{k-2} + \cdots + a_p c_{k-p}. \quad (10)$$

(When applying this iteration, recall that $c_0 = 1$.) As with the autoregressive form, the order of the MA process may approach infinity.

The MA model is an alternative way to characterize a stochastic process. It shows that a stationary process can be built up linearly from white-noise random errors, where the influence of these errors declines the farther removed they are in the past. Indeed, Herman Wold (1938) proved that any stationary process has such a moving average representation.

Wold’s theorem has an interesting implication. Suppose we start with the assumption that the stochastic process $y_t$ is stationary. We know from Wold that a moving average exists that can fully characterize this process. While such a moving average is not unique (there are
many MA models and forecast errors that are consistent with any given stationary stochastic process), only one such MA model is invertible. Invertibility means that the MA process can be inverted to form an autoregressive model with lag coefficients \(a_1, a_2, \ldots, a_k\) that approach zero as \(k\) gets large. Thus, the use of moving average and autoregressive models can be justified for all stationary processes, not just those limited to a specific class.

**RANDOM WALKS AND UNIT ROOTS**

Although economists and other social scientists mostly rely on stationary models, an interesting class of nonstationary autoregressive models often arises in time-series data relevant to these disciplines. Suppose that for the AR(1) model \(y_t = a_0 + a_1 y_{t-1} + \varepsilon_t\), the parameter \(a_1\) is equal to the value one. As seen in equation 7, such a process is nonstationary. However, if the first difference of this process, \(y_t - y_{t-1}\), is serially uncorrelated (the first difference of a stochastic process is simply the difference between its value in one period and its value in the previous period). If the constant term \(a_0\) is zero, this process is called a “random walk.” If \(a_0\) is not zero, it is called a “random walk with drift.” (Actually, for a process to be a random walk, its first difference must be independent white noise, which is a stronger condition than the absence of serial correlation. A process for which the first difference is serially uncorrelated, but not necessarily serially independent, is called a martingale difference.)

The change in a random walk is unpredictable. A time-series plot of such a process will appear to “wander” over time, without a tendency to return to its mean, reflecting the fact that its variance approaches infinity. If the process has, say, a positive drift term, it will tend to grow over time, but it will deviate unpredictably around this growth trend.

Although the idea of a random walk dates back at least to games of chance during the sixteenth century, the British mathematician Karl Pearson first coined the term in 1905 in thinking about evolution and species diffusion (Klein 1997, p. 271). The French mathematician Louis Bachelier (1900) led the way in using the notion of the random walk (although he did not use the term) to model the behavior of speculative asset prices. This idea was picked up by Holbrook Working in the 1930s, and it was formally developed in the 1960s by Paul Samuelson, who showed that when markets are efficient—when prices quickly incorporate all relevant information about underlying values—stock prices should follow a random walk.

The random walk is actually a special case of a more general nonstationary stochastic process called a unit root (or integrated) process. As seen above, for the AR(p) to be stationary, the roots of equation 8 must exceed one in absolute value. If at least one of these roots equals one (a unit root) while the others satisfy the stationarity condition, the process has infinite variance and is thus nonstationary. The first difference of a unit-root process is stationary, but it is not necessarily white noise. In general, if there are \(n < p\) unit roots, differencing the process \(n\) times will transform the nonstationary process into a stationary one. David Dickey and Wayne Fuller (1981) developed appropriate statistical tests for unit roots (see also Hamilton 1994, chapter 17), while Charles Nelson and Charles Plosser (1982) first applied these tools to economic issues.

**ESTIMATION AND FORECASTING**

The AR(p) model in equation 3 can be seen as representing all possible probability distributions that might generate the random sequence \(y_t\). Estimation refers to the use of an observed sample to infer which of these models is the most likely to have actually generated the data. That is, it refers to the assignment of numerical values to the unknown parameters of the model that are, in some precise sense, most consistent with the data.

Ordinary least squares (OLS) is an estimation procedure that selects parameter estimates to minimize the squared deviations of the observed values of the process from the values of the process predicted by the model. Under certain conditions, OLS has statistical properties that are deemed appropriate and useful for inference and forecasting, such as unbiasedness and consistency.

If an estimator of unknown parameters is unbiased, its expected value is identical to the true value no matter how large the sample is. Clearly, this is a desirable property. Unfortunately, the OLS estimator of the autoregressive parameters in equation 3 is not unbiased, because the random error process \(\varepsilon\) is not independent of the lagged values of the dependent variable. When the error and lagged dependent variables are not independent, the OLS estimator of the AR parameters will systematically underestimate or overestimate their true values.

Nonetheless, OLS remains the common method for estimating AR models, because the OLS estimator, though biased, is a consistent estimator of the actual values. With a consistent estimator of a parameter, the probability that it will deviate from the true value approaches zero as the sample size becomes large. For a stationary process, all that is needed for consistency of the OLS estimator of the autoregression is that \(\varepsilon\) be uncorrelated with \(y_{t-1}, y_{t-2}, \ldots, y_{t-p}\) for all \(t\) in the sample. As noted above, in theory this condition will hold because of the assumption that \(\varepsilon\) is serially uncorrelated. In practice, the condition is likely to hold if a sufficient number of lags are included in the estimated model. The upshot is that OLS will provide good estimates of the AR parameters, pro-
vided the sample is sufficiently large and the model is properly specified.

In the social sciences, the primary use of estimating AR models is to help forecast future values of a random variable by extrapolating from past behavior (using the conditional mean in equation 4). The foundations for exploiting the structure of AR and MA models for forecasting are based on the work of George Box and Gwilym Jenkins (1976). Although newer techniques have supplanted the exact methods of Box and Jenkins, their work has been extremely influential.

Because the true model of a particular stochastic process is unknown, forecasters must first determine the model they will estimate. The overriding rule of model determination suggested by Box and Jenkins is parsimony, which involves finding a model with the fewest parameters possible to fully describe the probability distribution generating the data. For example, while the data may, in concept, be generated by a complicated autoregressive process, a slimmed-down mixture of autoregressive and moving average components—an ARMA model—may provide the most efficiently parameterized model, and thus yield the most successful forecasts:

\[ y_t = a_1 y_{t-1} + \cdots + a_p y_{t-p} + e_t + c_1 e_{t-1} + \cdots + c_q e_{t-q}. \]  \hspace{1cm} (11)

Here, the autoregressive component contains \( p \) past values of the process, while the moving average component contains \( q \) past values of the white noise error; hence this model is expressed as an ARMA\((p,q)\).

With the methods of Box and Jenkins, it is important that the data be stationary since unit-root nonstationarity can overwhelm and mask more transitory dynamics. The autoregressive-integrated-moving average process, or an ARIMA\((p,d,q)\) model, is an ARMA\((p,q)\) model applied to a process that is integrated of order \( d \); that is, the process contains \( d \) unit roots. For example, the simple random walk model above can be described as an ARIMA\((0,1,0)\) process, because it is white noise after being transformed by taking its first difference.

EXTENSIONS TO THE BASIC AUTOREGRESSIVE MODEL

Thus far, the focus here has been on univariate autoregressive models (those having only one random variable). It is often advantageous to consider dynamic interactions across different variables in a multivariate autoregressive framework. The AR model is easily generalized to a vector stochastic process:

\[ y_t = A_1 y_{t-1} + \cdots + A_p y_{t-p} + e_t. \]  \hspace{1cm} (12)

In this case, \( y_t \) is now taken to be an \( n \times 1 \) vector of random variables, each of which varies over time, and each of the \( A \) matrices is an \( n \times n \) matrix of coefficients. The random behavior of the process is captured by the vector white noise process \( e_t \), which is characterized by the \( n \times n \) covariance matrix \( E e_{t} e_{t}' = \Sigma \). This model is commonly denoted as a vector autoregressive (VAR) model.

To get a clear idea of the nature of this multivariate generalization of the scalar AR model, suppose that each of the coefficient matrices \((A_k, \text{ for } k = 1, \ldots, p)\) is diagonal, with zero values in the off-diagonal cells. The VAR is then simply \( n \) separate univariate AR models, with no cross-variable interactions. The important gain in using VAR models for forecasting and statistical inference comes from the type of interaction accounted for by nonzero off-diagonal elements in all the \( A_k \) matrices. VAR models can also capture cointegrating relationships among random variables, which are linear combinations of unit-root processes that are stationary (Engle and Granger 1987).

In economics, VAR models have been effective in providing a framework for analyzing dynamic systems of variables. For example, a typical model of the macro economy, potentially useful for implementing monetary policy or forecasting business cycles, might be set up as a VAR with the four variables \((n = 4)\) being gross domestic product, the price level, an interest rate, and the stock of money. The VAR would capture not only the serial dependence of GDP on its own past, but also on the past behavior of prices, interest rates, and money. Christopher Sims (1980) produced the seminal work on the use of VAR models for economic inference, while James Stock and Mark Watson (2001) have reviewed VAR models and their effectiveness as a modern tool of macroeconometrics.

Finally, many random variables exhibit serial dependence that cannot be captured by simple, linear autoregressive models. For example, returns on speculative asset prices observed at high-frequency intervals (e.g., daily) often have volatilities that cluster over time (i.e., there is serial dependence in the magnitude of the process, regardless of the direction of change). The autoregressive conditional heteroskedasticity (ARCH) model of Robert Engle (1982) can account for such properties and has been profoundly influential. If the scalar \( \varepsilon_t \) follows an ARCH\((p)\) process, then the conditional variance of \( \varepsilon_t \) varies with past realizations of the process:

\[ e_t = z_t h_t^{\frac{1}{2}} \]  \hspace{1cm} (13)

\[ h_t = E(e_t^2 | e_{t-1}, \ldots) = \alpha_0 + \alpha_1 e_{t-1}^2 + \cdots + \alpha_p e_{t-p}^2. \]  \hspace{1cm} (14)

Indeed, it is straightforward to show that an ARCH process is tantamount to an autoregressive model applied to the square of the process, in this case \( \varepsilon_t^2 \). Tim
Autoregressive Moving Average (ARMA) Model

Bollerslev’s (1986) generalized ARCH (GARCH) model extends Engle’s ARCH formulation to an ARMA concept, allowing for parsimonious representations of rich dynamics in conditional variance:

\[ h_t = \alpha_0 + \alpha_1 \epsilon_{t-1}^2 + \cdots + \alpha_p \epsilon_{t-p}^2 + \beta_1 h_{t-1} + \cdots + \beta_q h_{t-q}. \]  

(15)

Even this model has been extended and generalized in many ways. Numerous applications of the GARCH family of models in economics, finance, and other social sciences have substantially broadened the reach of autoregressive-type models in the statistical analysis of time series.

SEE Autoregressive Models.

**AVERAGE AND MARGINAL COST**

Total (or global) cost, represented mathematically as \( C_T \), represents the total expenses needed to produce a given output. It is the sum of two kinds of costs: Fixed costs, represented as \( C_F \), are independent of the volume of output; they include expenses such as rents, insurance, maintenance of equipment, interest payments, and that portion of overhead and labor costs that is independent of the level of activity.

Variable costs, represented as \( C_V \), increase with activity. In the short run, modifications in the level of output are realized by modifying employment and raw material spending, with fixed equipment and plant costs. Some costs may be strictly proportional to production (for instance, raw material consumption); in other cases, cost variation may be more complicated, either for technical reasons (e.g. fuel consumption is not strictly proportional to speed), or for financial reasons (e.g. paying overtime hours). Let \( C_V = \psi(Q) \). A frequent assumption is that the rate of increase is always positive (\( \psi' > 0 \)) but variable: In a first phase of activity it decreases (\( \psi' < 0 \)), and increases in a second phase (\( \psi' > 0 \)); consequently, and obviously, it goes through a minimum (\( \psi' = 0 \)) between the two. In some cases, variable cost is considered as a constant, independent of the activity level for some production ranges.

Average total cost, or \( C_A \), is unit cost, that is, total cost divided by number of units produced: \( C_A = C_T / Q \). In a similar way, one can define average fixed cost as \( C_{AF} = C_F / Q \) and average variable cost as \( C_{AV} = C_V / Q \).

Marginal cost (\( C_m \)) is the additional cost of producing one more output unit. It depends on cost in the fol-
following way: An additional production of $\delta Q$ units means an additional cost of $\delta C_T$ euros (or dollars), thereby marginal cost is represented as $C_m = \delta C_T / \delta Q$. Given infinitely small increases of output, marginal cost is defined as derivative of total cost function: $C_m = \frac{\delta C_T}{\delta Q} = \phi'(Q)$. Marginal cost is independent of fixed cost and depends only on variable cost.

The following two cases will illustrate these principles: one using variable average costs, another using (total) variable costs strictly proportional to production, and, consequently, linear variable cost function.

**VARIABLE AVERAGE COSTS**

When production starts, the average cost curve decreases because fixed costs are recouped through increasing sales of production units. With further production increases, however, variable costs increase more than proportionally to the output level because of increasing production difficulties; eventually this factor prevails and the cost curve increases. Consequently, at a given production level average cost reaches a minimum.

The marginal cost curve in such cases follows the course indicated in Figure 1 decreasing at first when production starts and then increasing with output level. When production starts, any increase in production level implies a decrease of average cost; consequently marginal cost is inferior to average cost, and the marginal cost curve is under the average cost curve. With high production levels, marginal cost is superior to average cost (since it is very costly to produce additional output). Consequently, marginal cost curve intersects average cost curve on the minimum of this one.

This can be demonstrated mathematically as follows:

$$C_m = \frac{C_A}{Q} = \frac{C_F + C_V}{Q} = \frac{C_F + \varphi(Q)}{Q}$$

**VARIABLE COSTS STRICTLY PROPORTIONAL TO PRODUCTION**

When costs are considered in strict proportion to production, the variable cost function is linear, and with $a$ as a proportionality factor, $C_V = aQ$ and $C_T = C_F + C_V = C_F + aQ$.

Marginal cost is here constant, independent of production level

$$C_m = \frac{d(C_T)}{dQ} = \frac{d(aQ)}{dQ} = a$$

and equal to average variable cost defined as

$$C_{AV} = \frac{C_V}{Q} = \frac{aQ}{Q} = a$$

Both functions are identical and represented by one parallel to the quantity axis.

Average total cost $C_A$ is a constantly decreasing curve with two asymptotes, the vertical axis on one hand and the marginal cost line, or variable cost line, on the other (Figure 2).

This representation may be considered characteristic of cost functions for new products and especially for new technologies in information and communication. Development of new exploitation systems, new software, new aircraft, new medicines, cars, or drugs can cost millions of dollars. Reproduction may be quite cheap; a few dollars to manufacture a software program, more to produce a car; but the representation is also relevant since variable cost may in some cases amount to only 10 or 15
percent of total cost; the difference represents the costs of research and development, marketing, patent registration, and of course corporate profit. All these examples are characterized by very high fixed costs and constant marginal cost at very low level for large production ranges.

In the long run (which is not necessarily the same as a long time) changes in equipment and physical plant must be taken into account. The distinction between fixed and variable costs is no longer relevant because all production factors can be considered variable. With an increase in output, the average cost of production may decrease because of economies of scale due either to technical factors (improvement in task specialization, better division of labor, utilization of bigger and/or more specialized equipment) or for financial reasons (larger firms have more bargaining power with banks and suppliers).

Inversely, an excessively large production scale may create expenses: “diseconomies of scale” caused by administrative complexity, bureaucratic red tape, or organizational difficulties that may lead to increases in production costs. Such increases or decreases in costs are typical of internal economies (or diseconomies) of scale because they are the result of a firm’s own decisions. But costs may increase or decrease because of factors external to the firm that may modify its cost functions. Better organization of national production factors (raw material, labor), improvements to infrastructure such as the construction of roads and highways, or reductions in input prices or taxes qualify as external economies because they can improve a firm’s production costs regardless of the firm’s decisions. Conversely, external diseconomies may have a negative effect on production cost, such as deterioration in infrastructures, traffic jams, pollution, and tsunamis.

AVIATION INDUSTRY

The aviation industry is defined as the design, manufacture, use, or operation of aircraft; the term aircraft refers to any vehicle capable of flight. Aircraft can either be heavier than air or lighter than air. Lighter than air craft include balloons and airships, and heavier than air craft include airplanes, autogiros, gliders, helicopters, and ornithopters.

As early as 400 BCE the Greek scholar Archytas built a wooden pigeon that moved through the air, which is the earliest aviation experiment. The Americans Orville Wright and Wilbur Wright are generally credited with making the first controlled, powered, heavier than air human flight on December 17, 1903. In 1905 Charles and Gabriel Voisin, two French fliers, started the world’s first aircraft company. The military value of aircraft was quickly recognized during World War I (1914–1918), and production increased significantly to meet the rising demand. More powerful motors, enabling aircraft to reach speeds of up to 130 miles per hour, were developed. After World War I, thousands of military planes were converted to civilian use. By 1917 the U.S. government adopted something totally new: airmail. The Contract Air Mail Act of 1925 was the first major legislative step toward the creation of the private U.S. airline industry. Henry Ford, the automobile manufacturer, jumped into aircraft manufacturing and produced one of the first all-metal planes. On May 21, 1927, the pilot Charles Lindbergh flew across the Atlantic Ocean. This event made aviation an established industry by attracting millions of private investment dollars. For the airlines to attract more passengers away from the railroads, larger, faster, and safer airplanes were needed, and aircraft manufacturers responded to the challenge. There were so many improvements to aircraft in the 1930s that many believe it was the most innovative period in aviation history. Newton’s Third Law theorizes that a rearward-channeled explosion can propel a machine forward at a great rate of speed. The British pilot Frank Whittle applied this law to the first jet engine in 1930. During World War II, aircraft production became the world’s leading manufacturing industry.

Aviation is broadly grouped into three categories: general aviation, air transport aviation, and military aviation. By 1947 all the basic technology needed for aviation had been developed, including jet propulsion, aerodynamics, and radar. Civilian aircraft orders drastically increased from 6,844 in 1941 to 40,000 by the end of 1945. Among the minor military contractors was the
Boeing Company, which later became the largest aircraft manufacturer in the world. With all the new technologies developed by this time, airliners were larger and faster and featured pressurized cabins. New aerodynamic designs, metals, and power plants resulted in high-speed turbojet airplanes. By 1950 the airliner was well on the way to replacing the railroad and the ocean liner as the primary means of long-distance travel. The economic, social, and political consequences included the creation of global markets, opportunities for global travel undreamed of a generation before, and increasing cultural homogeneity.

In 1938 the Civil Aeronautics Authority, an independent regulatory bureau, was developed. The airline industry resembled a public utility, with a government agency determining the routes each airline flew and overseeing the prices charged. On October 24, 1978, the Airline Deregulation Act was approved, and the industry became market driven, with customer demand determining the levels of service and price. A major development that followed deregulation was the widespread development of hub-and-spoke networks, which enable the airlines to serve far more markets than they could with the same size fleet if they offered only direct, point-to-point service. Another important development following deregulation was the advent of computer reservation systems. These systems help airlines and travel agents keep track of fare and service changes, which occur rapidly. The systems also enable airlines and travel agents to efficiently process the millions of passengers who fly each day. In manufacturing, several mergers in the 1990s led to the disappearance of several historic U.S. airplane builders, such as McDonnell Douglas, which merged into Boeing. International partnerships became increasingly significant, with Airbus capturing one-third of the world market in jet airliner sales in the 1990s.

A number of researchers examined the impact of the 1978 Deregulation Act on the productivity of U.S. carriers and the demand for their services as well as how the international deregulation of the industry that accelerated in the ensuing years impacted the supply and demand for airline service worldwide. The studies pointed to an increase in efficiency of airline carriers due to increased competition, a provision of more service at lower prices, and an eroding of service quality as carriers competed on the basis of price instead of on the basis of in-flight amenities and flight frequency with relative low load factors.

On September 11, 2001, terrorists hijacked four commercial airplanes and deliberately crashed two into the towers of the World Trade Center in New York City and one into the Pentagon building in Washington, D.C. The fourth hijacked plane crashed in Somerset County, Pennsylvania. After the hijackings, U.S. airports and airlines sought new ways to protect against terrorist attacks. Congress passed legislation requiring federal employees to handle all passenger and baggage inspection in U.S. airports by the end of 2002.

Fears of terrorism and a sluggish world economy contributed to a decline in air travel in the early 2000s. In 2003 British Airways and Air France discontinued all Concorde flights because the flights were no longer profitable.

Although many countries continue to operate state-owned airlines, most large airlines in the early twenty-first century are privately owned and therefore governed by microeconomic principles to maximize shareholder profits. The airline industry as a whole has a cumulative loss during its history, once subsidies for aircraft development and airport construction are included in the cost. The lack of profitability and continuing government subsidies are justified with the argument that positive externalities, such as higher growth due to global mobility, outweigh microeconomic losses. A historically high level of government intervention in the airline industry can be seen as part of a wider political consensus on strategic forms of transport, such as highways and railways, both of which are also publicly funded in most parts of the world.

U.S. airlines face substantial upheavals in the forms of mergers, failures, bankruptcy filings, reorganizations, and operating loss reports. This situation has raised concern that the future is bleak in terms of the number of carriers that will survive and prosper. Profitability is likely to improve as carriers find ways to be more cost-efficient and more competitive low-cost carriers proliferate.

AXIOMATIC THEORY OF PREFERENCES

See Tastes.
BABY BOOMERS
The baby boom in the United States, which occurred between 1946 and 1964, took many social scientists by surprise, especially demographers. Few social scientists expected that the general fertility rate in the United States would rise from a record low in the mid-1930s to a record high in 1957 and then fall to a new record low in 1976. About 75 million more babies were born during the baby boom than expected, based upon previous fertility rates. Social scientists have pointed to two events that may have contributed to the baby boom: the Great Depression and World War II. The economic hardship that accompanied the Great Depression had a profound impact on American families, inducing the conscious decision by many to limit family size or to remain childless altogether. Births were postponed not only during the Great Depression but also during World War II, when many men were fighting overseas and many women working outside of the home (Macunovich 2002).

The conclusion of World War II brought a feeling of optimism and a period of prosperity, manifested in part by a rise in births. After World War II, soldiers returned home with entitlements that enabled them to participate in a housing boom that was one of the single greatest opportunities for wealth accumulation ever. Women who had been working in the labor force, some for the first time, returned home, and many remained there for decades to come. Individuals and families enjoyed a growth of pensions and Social Security for retirement. This feeling of great affluence and hope removed, at least temporarily, an interest in postponing childbearing. The resulting baby boom created a population bulge, the impact of which would be felt for years to come.

At the beginning of the twenty-first century, baby boomers represented about 33 percent of the total U.S. population. They have left their mark on various social institutions as they reached key points in the life cycle. School-aged baby boomers resulted in overcrowded educational facilities. As baby boomers became teenagers and young adults, crime rates increased, especially crimes committed by individuals 15 to 24 years of age. Thanks to the relative prosperity of their parents, baby boomers became the first ever generation of children and teenagers with significant buying power.

Many baby boomers came of age during a time of immense social change marked by such historic events as the civil rights movement. Baby boomers were observed to have different lifestyles and attitudes relative to previous generations. Unlike their parents, baby boomers delayed marriage and childbearing while simultaneously increasing their educational levels.

There is evidence that even with increases in education and accompanying increases in incomes, baby boomers are a diverse group (Sykes 2003). About 18 million baby boomers (24%) are racial minorities. Racial minorities in general have lower levels of income, education, and wealth than their white counterparts. Even families with similar income levels often have very different levels of wealth. Baby boomers are more likely than their
parents to be sole heads of households. Single-headed households are disproportionately found among the poor. About 10 percent of baby boomers never graduated from high school.

By 2030 the youngest baby boomers will have reached retirement age, yet some will not be financially ready (U.S. Congressional Budget Office 2003). About 25 percent of baby boomers will not have adequate savings to finance their own retirement and will place a strain on existing social programs such as Social Security and Medicare. By 2019 Social Security will provide as much as 70 percent of the retirement funds for baby boomers at the lowest levels of income, and there will be 3 retired baby boomers for every 10 workers—facts that compromise the ability of this safety-net program to meet the needs of current and future workers. Policy makers have debated about the impact that aged baby boomers will have on Social Security and other programs. Plans to address the issue include privatizing Social Security, which some argue would place the retirement futures of at-risk groups like African Americans, Native Americans, Hispanics, women, the poor, and the elderly in economic peril.

The baby boom was a tremendous population shift occurring not only in the United States but also in other parts of the industrialized world. Individuals born between 1946 and 1964 have altered the age ratios of various populations and have profoundly affected social institutions and social programs as they reach various milestones. Proposed changes to long-standing social programs like Social Security and Medicare are thought to have a disproportionate negative impact on those at greatest risk, namely racial minorities and the elderly.

rural and urban areas and the nature of rural-urban linkages. In general, the beneficial forces are stronger for rural areas near urban cores, while the adverse flows dominate in regions more peripheral to the growing urban areas. Thus, backwash is more likely in rural areas outside of the rural-to-urban commuting zones.

The policy implications of backwash are that localities distant from urban growth centers will likely be adversely affected by regional economic-development policies that focus on innovation and entrepreneurial development in urban areas. These remote regions will need to devise economic-development programs that emphasize competitive advantages specific to their economies.

David L. Barkley

**BAHRO, RUDOLF**

**1935–1997**

Rudolf Bahro was born November 18, 1935, in Bad Flinsberg in Lower Silesia (now Poland). As a child refugee at the end of World War II (1939–1945), fleeing the advance of the Soviet armies, Bahro lost his mother and both his sisters. Bahro studied philosophy at Humboldt University in Berlin from 1954 to 1959, during which time he joined the East German Communist Party. He worked as an editor for municipal and party papers, and later became a consultant to the presiding board of directors at the only trade union academy in East Germany. In 1965 Bahro took over the post of acting head editor for the newspaper Forum. The unauthorized publication of a critical piece, Volker Braun’s “Kipper Paul Bauch,” led to his resignation in 1967. Afterward, he worked at the paper as a production supervisor.

By the 1970s Bahro had emerged as a prominent critic of the East German Communist Party (Sozialistische Einheitspartei Deutschlands, abbreviated SED). It was entirely clear, however, that the leadership of the SED had absolutely no intention of entering into a dialogue with Bahro on the issue of basic reform in late-Stalinist East Germany. Robert Havemann, the other prominent critic of the East German regime, was under house arrest in Grünheide near Berlin, guarded by operatives of the East German security police (the Stasi). On August 23, 1977—shortly after publishing “Against Oneself and against One’s People” in the West German news magazine Der Spiegel and discussing his forthcoming book, The Alternative, in several television interviews—Bahro was arrested by the Stasi.

Bahro, who developed his critique within a Marxist framework, accused the Communist Party leadership of betraying socialist ideals. Characterizing the states of Eastern Europe as systems of organized irresponsibility, he analyzed their political economy and aspects of their industrial production. He recommended far-reaching reforms of the administrative apparatus—indeed, an overhaul of the entire political structure. In Bahro’s view, the Eastern Bloc was not merely an example of deformed socialism, but rather a social reality based on entirely different principles. He accused the Soviet leadership of having, through its invasion of Czechoslovakia in 1968, robbed itself and the peoples of Eastern Europe of the experience of socialism with a human face. He demanded true economic democracy, without wage privileges for tiny elites, and also the elimination of the existing division of labor. Genuine institutional self-rule, Bahro declared, must gradually develop from below, with freedom of personal development a necessary condition. He believed that a coalition drawing from all political tendencies could lead the way out of self-imposed imprisonment. All this was conceived as a new vision of communism. Altogether some 300,000 copies of The Alternative were sold, and the book was translated into numerous other languages.

Bahro was sentenced to eight years in prison. The international league for human rights awarded him the Carl von Ossietzky medal, and numerous authors and political figures demanded his release. Bahro was granted amnesty in 1979 and left for West Germany, where he became one of the cofounders of the Green Party. Believing that a political solution to the ecological crisis could only be achieved through a broad coalition spanning existing political divisions, he embraced everyone from the left-wing student activist Rudi Dutschke to the right-wing ecologist Herbert Gruhl. In his early years in West Germany, Bahro also devoted much of his time to the peace movement. He favored unilateral disarmament for both sides.

Because the Greens operated on the basis of an “eco-cosmetic” and reformist mode of power-sharing, Bahro left that party in 1985. Bahro’s second major work, Logik der Rettung (The logic of salvation, 1987; revised and translated as Avoiding Social and Ecological Disaster,
1994), traced the connections between the ecological crisis facing civilization and Western political-economic systems. The industrial capitalist “megamachine” was globally overstepping the boundaries of nature, causing irreparable climate change. It would be necessary to decrease industrial production tenfold, through changes in economic structures and lifestyles. There would have to be a sociopsychological alteration of the attitudes characteristic of business, so that a new spirit could be born. Bahro also asserted the need for a democratically run ecological superauthority, to monitor and enforce ecological change.

In 1990 Bahro returned to East Germany. Between 1990 and 1997, he gave well-attended lectures at Humboldt University, in which he addressed questions of spirituality and communal action in a socioecological context, drawing on influential thinkers from Lao-Tse to Martin Heidegger to Erich Fromm. His lectures and interviews were published in several books: Rückkehr (The return, 1991), Apokalypse oder Geist einer neuen Zeit (Apocalypse or the spirit of a new age, 1995), and Wege zur ökologischen Zeitenwende (Means of the end of an ecological era, 2002). In another book that remains unpublished, he set out his views and asked which elements of Marxism and of the collapsed East German state ought to be maintained.

Bahro died of leukemia in 1997. In 2002, in Germany, Guntolf Herzberg and Kurt Seifert brought out a comprehensive biography of this prophetic thinker.

BALANCE OF PAYMENTS

The balance of payments is an accounting statement that records transactions (trade in goods, services, and financial assets) between a country’s residents and the rest of the world. Those transactions consist of receipts and payments—credits (entries that bring foreign exchange into the country) and debits (entries that record a loss of foreign exchange), respectively—that are recorded through the use of double-entry bookkeeping. Balance-of-payments data usually are reported quarterly in national publications and also are published by the International Monetary Fund.

THE CURRENT, CAPITAL, AND FINANCIAL ACCOUNTS

The balance of payments consists of the current account, the capital account, and the financial account (see the illustration). The current account includes trade in merchandise (raw materials and final goods), services (transportation, tourism, business services, and royalties), income (from salaries and direct, portfolio, and other types of investment), and current transfers (workers’ remittances, donations, grants, and aid). The current account is related to the national income accounts because the trade balance corresponds broadly to the net export value recorded in the national income accounts as one of the four components of the gross national product.
(GNP), along with consumption, investment, and government expenditures.

The capital account records all international capital transfers. Those transfers include the monetary flows associated with inheritances, migrants’ transfers, debt forgiveness, the transfer of funds received for the sale or acquisition of fixed assets, and the acquisition or disposal of intangible assets. The financial account records government-owned international reserve assets (foreign exchange reserves, gold, and special drawing rights with the International Monetary Fund), foreign direct investment, private sector assets held abroad, assets owned by foreigners, and international monetary flows associated with investment in business, real estate, bonds, and stocks.

The balance of payments should always be in equilibrium. The current account should balance with the sum of the capital and financial accounts. However, because in practice the transactions do not offset each other exactly as a result of statistical discrepancies, a separate line with those discrepancies is included in the statistical presentation.

If the current account is in equilibrium, the country will find its net creditor or debtor position unchanging because there will be no need for net financing. Equilibrium in the capital and financial accounts means no change in the capital held by foreign monetary agencies and reserve assets. In the case of disequilibrium arising when a country buys more goods than it sells (i.e., a current account deficit), the country must finance the difference through borrowing or sale of assets (i.e., there is an inflow of capital and thus a capital and financial account surplus). In other words, the country uses foreign savings to meet its consumption or investment needs. Similarly, if a country has a current account surplus, the capital and financial accounts record a net outflow, indicating that the country is a net creditor. The exchange rate regime is an important determinant of the adjustment toward the new equilibrium. With fixed exchange rates, central banks must finance the excess demand for or supply of foreign currency at the fixed exchange rate by running down or adding to their reserve assets. Under floating exchange rates, balance of payments equilibrium is restored by movements in the exchange rate.

### THEORIES AND ASSESSMENT OF THE BALANCE OF PAYMENTS

A number of theories have been developed to explain the adjustment process of the balance of payments. In a world without capital flows the elasticities approach provides an analysis of how changes in the exchange rate affect the trade balance, depending on the elasticities of demand and supply for foreign exchange and/or goods. An exchange rate depreciation increases the domestic price of imports and lowers the foreign price of exports. However, depreciation reduces imports only if import demand is

elastic; the same is the case for the behavior of exports after a decline in export prices. Thus, the final impact on the current account balance depends on the elasticity of demand in each country for the other country’s goods and services.

The absorption approach emphasizes the way in which domestic spending on domestic goods changes relative to domestic output. The trade balance is viewed as the difference between what the economy produces and what it spends. In an economy that is operating below its full potential an exchange rate depreciation tends to increase net exports (given the elasticity conditions noted above) and bring about an increase in output and employment. In an economy operating at full potential, in contrast, a depreciation tends to increase net exports, but because it is not possible to increase output, the result is higher prices of domestically produced goods.

In the modern global economy with well-developed financial markets and large-scale capital flows, financial assets play an important role in the analysis of the balance of payments. The lifting of controls on the movement of capital and financial flows has been fundamental to promoting world trade and eventually greater incomes. The unrestricted movement of capital allows governments, businesses, and individuals to invest capital in other countries, thus promoting not only foreign direct investment but also portfolio investment in the capital market.

With perfect capital mobility, monetary and fiscal policies affect the balance of payments through the interest rate channel. Under fixed exchange rates an increase in the money supply will reduce interest rates and lead to capital outflows, tending to cause a depreciation that will have to be offset by sales of foreign exchange by the central bank. This will then reduce money supply until it reaches its original level. Thus, monetary policy is ineffective in increasing output. Fiscal policy, however, is highly effective because a fiscal expansion tends to raise interest rates, leading the central bank to increase the money supply to support the exchange rate, reinforcing the impact of the expansionary fiscal policy. Under floating exchange rates, monetary policy is highly effective and fiscal policy is ineffective in changing output. A monetary expansion leads to depreciation and higher exports and output. Fiscal expansion, in contrast, causes an appreciation of the exchange rate and crowds out net exports.

The introduction of interactions between prices and changes in the exchange rate leads to a model that postulates that price flexibility ultimately moves an economy to full employment. The mechanism involves changes in the domestic money supply that take place as the central bank keeps selling foreign exchange to domestic residents in exchange for domestic currency. A monetary contraction thus reduces prices, improves competitiveness, and increases net exports and employment. Under floating exchange rates, in the short run a monetary expansion increases output and reduces interest rates, causing a depreciation of the exchange rate. In the long run, however, a monetary expansion increases the price level and the exchange rate, keeping real balances and the terms of trade unchanged.

The monetary approach to the balance of payments postulates that disequilibrium in the balance of payments is essentially a monetary phenomenon. It emphasizes the central banks’ balance sheet identity—a change in net foreign assets equals the difference between changes in high-powered money and in domestic credit—which shows that sufficient contraction of domestic credit will improve the balance of payments. This improvement comes about through higher interest rates and lower domestic income and employment. Finally, the asset market (or portfolio) approach incorporates assets besides money. In recognition of the fact that asset markets across countries are well integrated, changes in the demand for and supply of assets will affect interest rates, exchange rates, and the balance of payments.

MACROECONOMIC STABILITY
Maintaining a favorable balance-of-payments position is important for macroeconomic stability, and countries gear their policies toward achieving that goal. Although current account deficits that are financed through non-debt-creating capital flows may not pose an immediate threat, large and unsustainable deficits can transform into chronically unfavorable balance-of-payments positions that may affect the stability of the currency. Correcting such unfavorable positions is done through the adoption of stabilization programs that sometimes are supported by the International Monetary Fund through the provision of short-term financing to ease the burden of temporary problems.

BIBLIOGRAPHY
**Balance of Trade**

A nation’s balance of trade, also called “net exports,” is a measure of the net flow of goods and services between that country and the rest of the world. Given domestic output (or income) \( Y \), domestic spending on domestic output \( D \), exports \( X \), and imports \( M \), the balance of trade is \( B = Y − D − X + M \). The balance of trade is in surplus if \( B > 0 \), and it is in deficit if \( B < 0 \). This formulation suggests that fluctuations in domestic output can be absorbed by fluctuations in the trade balance, keeping domestic spending relatively stable. In 2005, the balance of trade relative to GDP (gross domestic product) for the United States, South Korea and Brazil was –5.7 percent, 2.6 percent, and 4.6 percent, respectively.

A nation’s income, the income of its trading partners, and the relative price of domestic goods (compared to foreign goods) determine its balance of trade. As domestic income \( Y \) rises, expenditure on all goods—including foreign-produced goods—increases. Thus, imports increase and the balance of trade decreases. Similarly, when the income of a nation’s trading partners increases, so do its exports, thus increasing the balance of trade. The relative price \( R \) of domestic to foreign goods is \( R = S/P^* \), where \( S \) is the spot exchange rate (the foreign currency price of the domestic currency) and \( P \) and \( P^* \) denote the native currency prices of domestic and foreign goods, respectively. With short-run price inflexibility, a change in the exchange rate \( S \) is fully reflected in a change in the relative price.

Since domestic and foreign outputs have a degree of substitutability, the nominal exchange rate affects both exports and imports. Generally, an exchange-rate depreciation (a decrease in \( S \)) switches spending away from foreign goods toward domestic goods and increases the balance of trade. Reflecting an excess of domestic spending over domestic income, a balance-of-trade deficit may be offset by a net inflow of labor and asset incomes from abroad. Otherwise, overspending must be funded through a depletion of national wealth, possibly in the form of increased indebtedness to foreign entities through the sale of domestic bonds or of outright sales of equity or other assets. This net inflow of foreign capital requires that foreign savers be willing to lend against, or buy, domestic assets. If they are unwilling to do so or if they are not allowed to do so because of domestic capital controls, the domestic currency will depreciate and eliminate the deficit. If this does not occur and if the exchange rate is fixed, the central monetary authority must sell its gold or foreign currency reserves, causing the domestic money supply and, over time, the domestic price level to decrease and reverse the deficit.

A nation may sustain a balance-of-trade deficit for short periods but not persistently. Rising indebtedness would cause foreign lenders to fear that their claims would not be honored, leading to a reduction of further investment in domestic assets. Moreover, the government’s corpus of gold and foreign currency reserves is finite. The existence of a long-term trade imbalance that is not offset by factor-income inflows is of concern because it reflects a fundamental divergence between domestic income and domestic spending. Many countries have learned sometimes from bitter experience, that persistent failure to harmonize income and spending can lead to corrective forces, sometimes resulting in economic crises in the form of large increases in interest rates, unemployment, or a sharp depreciation of domestic currency.

Policymakers must balance short-run conflicts in maintaining the trade balance at a targeted level \( B^* \) (possibly zero), while also maintaining domestic output at a level \( Y^* \) consistent with full employment and constant inflation. In a fixed-exchange-rate regime, these goals can be met by judiciously mixing domestic demand and exchange-rate levels. Assuming stability, the relationships

\[
Y^* = D + B \ (Y^*, S) \quad \text{and} \quad B^* = B \ (Y^*, S)
\]

together yield unique values of domestic demand and exchange rate, \( D_0 \) and \( S_0^* \) consistent with the goals. The level \( D_0 \) is achieved by adjusting fiscal policy; monetary policy cannot be used independently under a fixed exchange rate regime.

It may be inferred that if fiscal policy is set at \( D_0 \) but the exchange rate is overvalued \( (S > S_0^*) \), a trade deficit will result, accompanied by unemployment. It may also be inferred that if the exchange rate is undervalued \( (S < S_0^*) \), a trade surplus will accrue, along with inflationary pressure. Similarly, if the exchange rate is set at \( S_0^* \) but fiscal policy is too restrictive \( (D < D_0) \), a trade surplus will coexist with unemployment, while an expansive fiscal policy \( (D > D_0) \) results in a trade deficit and inflationary pressure.

If the exchange rate is flexible, both fiscal and monetary policies will quite likely affect the balance of trade. Both affect the interest rate \( r \) and, thereby, the exchange rate, which moves to equilibrate international asset markets by equating the expected returns on domestic and foreign assets. If the foreign interest rate exceeds the domestic interest rate, the difference is offset by an expected appreciation of the domestic currency; otherwise, the foreign asset yields excess returns. Given an unchanged expected future exchange rate, a decrease in \( r \)
causes the domestic currency to depreciate (it decreases $S$) immediately, thus generating expectations of a forthcoming appreciation. The depreciation increases the balance of trade.

Fiscal and monetary expansions, by increasing $Y$, cause an incipient worsening of the trade balance, which works to depreciate the domestic currency. Additionally, a monetary expansion decreases $r$ and causes capital outflows, compounding this depreciation and causing the balance of trade to improve. However, a fiscal expansion increases $r$, stimulates capital inflows, and appreciates domestic currency. The appreciation caused by sufficiently high capital mobility can overwhelm the depreciation effect of output expansion and worsen the balance of trade. Thus, a budget deficit can give rise to a trade deficit, invoking the label “twin deficits.”

**BALLET**

**SEE** Dance.

**BALLOTS**

A ballot is a device for casting a vote. Traditionally, the word referred exclusively to a piece of paper, but modern usage also applies the term to electronic voting methods. Generally, ballot format covers both how the choices for various electoral contests are arranged and how choices (votes) are recorded.

The information conveyed on a ballot varies by voting system. Some electoral rules require rankings of multiple candidates, others require the selection of one or more alternatives from a set, and others involve multiple choices, such as picking one party from a list and also ranking various individuals from that party. There is also much variation in how access to the ballot is gained, precisely what information about candidates is listed, how choices are ordered, and whether voters check boxes, punch out perforated tabs of paper, press buttons, write out numbers or names, and so on.

Probably the most fundamental aspect of ballots is whether they are cast in secret. Voting in early democracies was done openly, and ballots were even produced by parties in distinct colors and shapes, to allow observers to determine how individuals voted.

Secret ballots were first introduced in Australia, and the term *Australian ballot* is still often used to refer to any ballot cast privately, even in places that share no other electoral rules with modern Australia. Many polities have made early and absentee voting (usually done by mail) easier in recent decades, in an effort to boost turnout. However, since absentee ballots are not cast in secret, they make old-style fraud, such as vote buying, much easier.

American elections usually feature many contests. In parliamentary democracies, it is more common for ballots to feature few races, sometimes only one. When ballots do cover multiple races, an important distinction is whether all candidates seeking a given office (as representatives of different parties) are grouped together or, instead, all candidates from a given party (seeking different offices) are grouped together. Sometimes ballots include an option to vote for all candidates from a party in a single stroke, though this so-called straight-ticket option has gradually become less common in American states.

In the 2000 American presidential election, Palm Beach County, Florida, used the now-famous butterfly ballot, wherein the names of competing candidates alternated from appearing to the left or the right of their associated punch-holes as one moved down the list. Analysis later suggested that many voters were confused by the format.

On a spoiled ballot, the choice(s) of the voter cannot be discerned. More complicated electoral systems and ballots featuring more contests tend to see higher rates of spoilage (including overvoting, the selection of more candidates than are legally permitted) and of undervoting (selective abstention, which is usually allowed).

As jurisdictions increasingly employ varieties of electronic voting, new issues with ballot formats have emerged. One important issue is whether computer voting systems generate a hard paper copy of the choices of voters along with the electronic copy, as a means of limiting fraud or accidental vote loss.
BAMBOOZLED

Shelton Jackson (“Spike”) Lee (1957–) and his 40 Acres and a Mule production company have made thirty-five films since 1983. Two of his films—Do the Right Thing (1989) and Four Little Girls (1997)—have been nominated for Academy Awards (Best Original Screenplay and Best Feature Documentary, respectively). Lee’s films are known for their social commentary, sometimes presented in excessively didactic fashion, and their edgy exploration of recent developments in popular culture and politics. Extremely outspoken about social issues and public policy, Lee has made especially strong statements about the Tuskegee Syphilis Study and the U.S. government’s laborious response to the impact of Hurricane Katrina on Gulf Coast communities. Indeed, his much acclaimed recent documentary, When the Levees Broke (2006), specifically addresses the failure of state, local, and federal authorities to address the needs of the citizens of New Orleans when Hurricane Katrina flooded the city.

In 2000, Lee released the film Bamboozled, which tells the story of Pierre Delacroix, played by Damon Wayans. Delacroix is a black television writer who has grown frustrated with the business. Tired of repeatedly having his “best-foot-forward” black pilots rejected for less positive fare, Delacroix recreates “The New Millenium Minstrel Show” show in hopes of getting fired. He heads to the office of his white boss, Dunwitty (played by Michael Rappaport), accompanied by his assistant Sloan (played by Jada Pinkett) and Womack and Man Ray (played by Tommy Davidson and tap dancer Savion Glover, respectively), two homeless squatters he finds performing on the street. Dunwitty, whose office is a veritable museum of black sports history and whose wife is black, is the iconic, self-described white man who knows more about black people than black people know themselves.

After pitching his show as a satire and casting the pilot from dozens of actors who attend the audition, Delacroix shoots the pilot. To his surprise, despite featuring actors in blackface and scenes of chicken and watermelon stealing, the show is an immediate hit, much to the dismay of black activists Jesse Jackson and Al Sharpton, who made cameo appearances as themselves. The show also angers the Mau Mau, a misguided group of militants led by Sloan’s brother, who make plans to sabotage the show after being rejected at their audition to serve as the program’s house band. As the show and Man Ray—now known as Mantan—grow in popularity at the hands of a stable of white writers, the Mau Mau plot to end his career by whatever means they have at their disposal.

Their goal comes to fruition as they succeed in kidnaping and killing Mantan on a live broadcast shortly before being gunned down by the police themselves. Only one-sixteenth black, the member of the Mau Mau who is phenotypically white is spared by the police despite his pleas for them to kill him also. Here Lee is evoking an actual event: In the early 1990s a California street gang was shot by the police and only two gang members survived, one emerging unscathed and the other suffering a leg wound. Both were white. The sight of her brother’s and his comrades’ deaths drives Sloan to enter a despondent Delacroix’s house and shoot him fatally. Delacroix’s final acts are to wipe her fingerprints off of the gun and lament his decision to develop the minstrel show that resulted in tragedy.

While Lee’s films Do the Right Thing (1989) and Malcolm X (1992) are more heralded, Bamboozled stands as his most shrewd social critique and, excluding the magnificent documentaries Four Little Girls and When the Levees Broke, his lone masterpiece. Disturbing, terrifying, and polarizing, Bamboozled opened to little fanfare in 2000. Early trailers for the film elicited uncomfortable squirms from audiences and prayers that the sight of black characters on screen in blackface meant that a hearty satire was in store. Lee even begins the film with a Damon Wayans voiceover reciting the definition of satire. What Lee has in fact constructed is a horror story.

In Pierre Delacroix, Lee creates a modern Dr. Franklinstein. Mary Shelley’s allegory plays out as Delacroix’s creation—the minstrel show—spirals out of control and wreaks havoc. Delacroix even refers to himself as Franklinstein before the show’s premier. Lee has been criticized for the movie’s somber ending, but, in keeping with Shelley’s template, the monster and the monster’s...
creator must suffer. Both must be perpetrators and victims of the destruction that has been released.

The character Man Ray exemplifies this theme. Literally lifted off the streets, he and Womack are savvy enough to recognize that what they are doing is ethically wrong but hungry enough to ignore their reservations. Man Ray’s simultaneous status as victim and perpetrator becomes the metaphor for the general condition of the black artist in the entertainment world. Ironically, Man Ray accuses Delacroix of sounding like a packaged voice from the popular media without realizing that that is precisely what Delacroix is and who Man Ray himself is becoming. Indeed, it is Delacroix’s parents who expose Delacroix to the audience as a fake whose given name at birth was Peerless Dotham.

By naming Savion Glover’s character Man Ray and then renaming him as Mantan, Lee pays homage to black artists who were denied proper credit for their comic talents during their lives, like Mantan Moreland. Womack is called “Sleep ‘n’ Eat” on Delacroix’s minstrel show. The character name refers to the billing assigned to Willie Best, who for a large part of his film career was called only “Sleep ‘n’ Eat,” if he was listed at all. Moreland, Best, and Lincoln Perry (known widely as Stepin Fetchit) were gifted actors, but their comedic talents were devoted exclusively to roles in which they portrayed the most demeaning stereotypes associated with black men—lazy, foot-shuffling, slow thinking, cowardly, and wholly subservient to whites. They were consistently the “Uncle Toms” or “Coons” (Bogle 2001), posing no danger to whites no matter the magnitude of the latter’s acts of racist indignity.

The Mau Maus exemplify well-intentioned but misguided revolutionaries everywhere, and their behavior culminates in the killing of the target they can reach most easily. But, Man Ray/Mantan was really no more than a well-paid pawn in a programming venture executed by studio executives. As Delacroix’s auditions demonstrate, there is always a long list of actors eager to play any part.

*Bamboozled* actually resembles a documentary because its tiny budget resulted in the film being shot with fifteen MiniDV digital cameras. While the budget permitted only a relatively low-quality print, Lee and consultant Michael Ray Charles used this limitation to their advantage in creating the film’s motif. Visual artist Charles used his experience both as a historian and as an actual subject in a documentary to lend accuracy and a gritty, eerie look to the film. His artwork adorns Sloan’s living room, but that room, like the offices in Delacroix’s building, including Dunwitty’s office with its prints of black athletes, still seems lifeless and barren.

The film’s music also contributes to the chilling tone. The minstrel show’s theme song, “I Wish I Was in Dixie”—performed by the Roots—is obvious, but the smooth Terrence Blanchard horn riffs that play during Mantan’s death and Delacroix’s subsequent moment of shame and remorse are a sonic counterpoint to the horrific images on the screen. Delacroix chooses to black his own face in this moment of mourning. In contrast to the actors on his minstrel show or their audience, there is nothing celebratory about his act of blackface; it is, instead, an act of penance manifesting his spiritual and moral nadir.

If the film can be faulted, it is for being overly ambitious. Arguably, the film tries to skewer too many subjects at once. The commercials for “Bomb” malt liquor and “Timmy Hilnigger” jeans are overkill. However, Lee is not interested in subtlety. He has stated publicly that he believes the movie does not overstate conditions in the film or television industry and that the characters are the types of people he encounters daily in Hollywood. Furthermore, he says that the idea of a live prime-time snuff broadcast is not that far in the future, comparing it with graphic war or riot footage that is aired frequently.

*Bamboozled* grazes over the subject of gender inequality. Lee’s movies have often been criticized for their gender politics, but in this film Sloan is dynamic and complex, not just a victim or opportunist. Her initial objections to Delacroix’s plan are mollified by his caress on her shoulder. He refers to her as his “little lamb,” and it is only in the third act that the actual history of her relationship with Delacroix is made known.

Like all the characters in the film, Sloan raises the ethical question of how far a person will go and at what price. Is ignorance of the full consequences an excuse? Do black artists have a responsibility to be conscious of racial representation in everything they do? Are black artists during the first half of the twentieth century granted clemency because of the constraints of their times, and, if so, what is the point when forgiveness ends and pointed criticism begins? Womack/Sleep ‘n’ Eat does leave the minstrel show, but only after he has made a substantial sum of money. Sloan also withholds her own moral concerns and personally teaches Man Ray and Womack how to black their faces correctly, voicing objections based only on the potential adverse community reaction.

When the film was made, Lee may have intended it to convey a dystopic vision of a not-so-distant future, but many viewers in the years following its release recognized familiar images in real-life entertainment. Created in a post–Rodney King, pre-9/11 era, the film shows how easily the public can become desensitized. The audience at the opening of the minstrel show moves quickly from appalled silence to reluctant nervous laughter to full participation in the racist skits. The transition is eased by the fact that the performers are talented (as were Moreland,
Best, and Perry), and the skits are, despite their political and social ramifications, inspired and funny.

Ultimately, the film is an extended cautionary tale for the American media's continuing to put forth images that are similar to the minstrel tradition. It serves as a warning to individuals who bear direct or proximate responsibility for perpetuating stereotypes. In Bamboozled Lee is confronting the actions of producers, directors, and established actors, not just the desperate dirt-poor squatters, represented by Mantan and Sleep ‘n’ Eat, eager for a break.

BANANA INDUSTRY

The production, consumption, and sale of bananas are important activities for many developing and low-income countries, generating employment, sustaining rural livelihoods, enhancing nutrition, and contributing to food security. The banana in 2002 was the fourth most important food crop in terms of value and ranked highest among fresh fruit exports in volume and in terms of export revenue to developing countries. Most bananas produced are consumed locally, with only 11 percent exported. At the start of the twenty-first century 85 percent of production was carried out by small producers using limited technological inputs.

COMPETITIVE STRUCTURE

Banana production for export employs a variety of systems, including small-scale, labor-intensive production on farms between 0.1 and 10 hectares and large-scale plantations ranging from 100 to 4,000 hectares. The latter produce 80 percent of fruit traded, employing high levels of technological innovation, including cable cars and extensive irrigation. These systems result in varying levels of efficiency, evident in a wide range of yields from as high as 60 tonnes per hectare on modern plantation systems to a low of 4 tonnes on smaller farms. The banana trade is highly concentrated. In 2002 four transnational corporations (TNCs), Del Monte, Chiquita, Dole, Fyffes, and Noboa, an Ecuadorian company, controlling more than 80 percent of the trade, which includes shipping, ripening, and distribution. Dole, Chiquita, and Del Monte, whose predecessors United Fruit Company and Standard Fruit and Steamship Company pioneered the vertically integrated production and distribution system that characterized the origins of the industry in Latin America and the United States, continue their involvement in fruit production, accounting for over 50 percent of the fruit traded. Independent banana producers often engage in contract arrangements with banana companies to export their bananas. The structure of the market is grossly unequal, with international trading companies, distributors, and retailers earning 88 percent of the retail price, producing countries under 12 percent, and laborers less than 2 percent.

The conditions of workers involved in banana production vary widely. Low labor costs and cheap prices for bananas are key features of the industry's competitiveness. The first is oftentimes achieved by poor working conditions, restrictions on workers' rights to join trade unions of their choice, discrimination against women, and the use of child labor. Low prices, which result from the intense competition for markets, characterize the industry and translate to poor wages for workers, and increase the survival challenge for small-scale, independent producers.

INTERNATIONAL TRADE IN BANANAS

Developing countries are the main suppliers of banana exports and developed countries the main markets for imports, accounting for over 80 percent in 2002. There are three main markets for banana exports: Europe, North America, and Asia, in order of importance. The European Union (EU) became the largest market for banana imports in 2004 with the accession of ten new member states, absorbing one-third of the world trade in 2005. Together the EU and the United States accounted for over 60 percent of imports, while Japan and the Russian Federation combined imported roughly 12 percent.

Latin America (Ecuador, Costa Rica, Colombia, and Panama) is the largest exporting region, with Ecuador being the largest exporter in the world, exporting 4,653,900 tonnes in 2005. The Philippines was a distant second, exporting 1,904,700 tonnes, followed by Costa Rica. Latin American producers supply most of the United States and the Russian Federation. Ecuador and
the Philippines are the major suppliers of the Japanese market. Latin America supplied 67 percent of the EU market in 2004; African Caribbean Pacific (ACP) countries (Cameroon, Ivory Coast, and several Caribbean countries, including the Windward Islands) supplied 17 percent; and producers within the EU (Martinique and Guadeloupe, Canary Islands, Madeira) supplied 16 percent.

REGIMES GOVERNING THE IMPORTATION OF BANANAS

A variety of arrangements govern the importation of bananas, ranging from wholly unregulated to highly regulated markets. The U.S. market is the most open, with no tariffs, quotas, or sanitary and phytosanitary (SPS) requirements (to ensure food safety and animal and plant health and product standards). Japan operates a seasonal preferential tariff rate. The European Community (EC), up to January 2006, was the most regulated market for bananas, with a complex system of quotas, tariffs, and licenses designed to provide preferential access to suppliers from the ACP countries.

EC Council regulation 404/93, which brought into being the Common Market Organisation for bananas and unified the EU banana market in 1993, changed significantly after the United States, on behalf of banana companies, and Ecuador, Honduras, Guatemala, and Mexico successfully challenged the legitimacy of some of its provisions under World Trade Organization (WTO) rules. It is now a simple tariff quota system, with a tariff of euro 176 per metric ton, and a duty-free quota of 775,000 tonnes for ACP producers on a first come, first served basis. This represents a significant reduction in the protection ACP countries had enjoyed. Latin American producers, particularly Ecuador, and some ACP producers are the main beneficiaries of this change at the expense of higher-cost, small farm driven production systems that exist in some Caribbean ACP exporting countries. In the Windward Islands, which has some of the smallest farming systems, production declined by 46 percent between 1994 and 2004, and the industry is not expected to survive further tariff reductions.

ANTICIPATED CHANGES IN THE INDUSTRY

The international trade in bananas is dynamic, with a steady increase in production but fluctuating prices. The output in the period between 1984 and 2000 saw a dramatic growth in the industry, which resulted in an increase in banana exports of 5.3 percent, more than twice that of the previous twenty-four years. This growth has been attributed to increased areas of production and, to a lesser extent, an increase in yields, rising demand in newly liberalized markets in eastern Europe and China, and increased income in major banana importing countries in the 1990s. Projections to 2010 show the banana trade growing from 12.6 million tonnes in 2004 to 15 million tonnes, although at a slower rate than the previous decade, with Ecuador and the Philippines continuing to lead production.

Increasing Chinese domestic production suggests that China may become an important player in the export trade. The EU is expected to continue the trend of attracting a greater share of imports, especially in light of the reorganization of its market. Developing countries and transition countries, however, are expected to play a larger role as import markets for bananas, with some developing countries becoming major players after 2010. The production of bananas under organic and fair-trade labels is expected to increase. This market remains small, however, with organic bananas accounting for only 1 percent of the trade in 2002 and fair-trade bananas largely confined to the EU market. The evolution of supermarkets as major players in the production process, especially in standard setting, intensifying price competition, and the increasing use of contractual arrangements with suppliers is likely to strengthen, resulting in a further concentration of the trade at all stages: production, supply, and retail.

ENVIRONMENTAL AND LABOR PRACTICES

The extensive use of inputs to enhance quality and to control diseases and pests has contributed to concerns about the industry’s impact on the environment. These surround the monocultural cultivation of the crop, which increasingly is focused on a single variety, the Cavendish, and its implications for biodiversity and vulnerability to disease and adverse weather; the intensity of production and the implications for soil fertility; the heavy usage of agro-chemicals, including pesticides, fungicides, and fertilizers, and the dangers they hold for contaminating water supplies and for workers’ health; and the proper disposal of plastic bags and other waste products.

Cultivation of organic and fair-trade bananas has developed in response to these concerns. Both systems are geared at mitigating the negative effects of production on the environment, with fair trade also focused on improving labor conditions, especially low wages, which can potentially increase the sustainability of small scale production. Environmental and food safety concerns have also led to a proliferation of standards to address some of the more egregious aspects of cultivation. The main standard setting institutions are the International Organization for Standardization (ISO 14001), the Food and Agriculture Organization/World Health Organization (FAO/WHO)

CHALLENGES FACING THE INDUSTRY

The main challenge facing the industry, to quote the Costa Rican union leader Gilberth Bermudez Umana from a paper delivered at the International Banana Conference II, lies in “achieving a system of banana production based on social justice and on a development model in harmony with nature” (Umana 2005). Such a system should also result in a more equitable sharing of profits along the banana production and distribution chain in favor of laborers and small-scale producers. The difficulty, however, is that this is to be accomplished in an industry where cheaper fruit is attained at the expense of the living conditions of banana producers and the environment.

BANANA PARABLE

The banana parable is found both in A Treatise on Money (Keynes 1930) and in John Maynard Keynes’s exposition to the McMillan Committee, which was established in 1930 by Prime Minister Ramsay MacDonald to evaluate the performance of the economy in Great Britain. The committee consisted of senior ministers and outside experts, of which Keynes was one. In the Treatise it is presented as an illustration that saving by itself does not guarantee that investment will increase proportionally. In the explanation to the MacMillan Committee it is presented in relation to a closed or an open economy with a gold standard and in the context of an evaluation of the role of the banking system in effecting saving and investment.

In the 1920s Great Britain experienced high levels of unemployment with large fluctuations in its economy. Keynes turned his attention to those issues in A Treatise on Money, in which he attempted to reexamine the relationships among money, prices, and unemployment. He believed that the main cause of unemployment and economic fluctuations was the relationship of saving to investment. When individuals save more than the amounts businesses want to invest, that leads to excess capacity and too few buyers of the goods produced.

The saving-investment relationship was an important concern that was brought out in Keynes’s “banana parable.” In the story Keynes envisions a simple economy that produces and consumes only bananas and in which “ripe” bananas keep only for a week or two. There is a thrift campaign in that closed economy to increase saving with no corresponding increase in investment in bananas. With the same amount of bananas being produced as before the thrift campaign, savings will lower demand, causing the price to fall. This might seem desirable, Keynes points out, for it may increase saving and reduce the cost of living. However, if wages have not changed along with the falling price, the cost of production becomes greater than the revenue represented by the price and businesses will lose an amount of money equal to the saving rate. The consequence is that businesses need to cut costs by lowering wages or by firing workers, and this only makes matters worse. As the overall income level falls, this pushes the economy into a deeper recession. Keynes argued that the best way out of the economic downturn is for the central bank to pump more money into the economy to increase investment.

This parable presented a significant critique of classical economics by showing that flexible wage rates do not lead automatically to full employment. It also raised questions about the classical view of Say’s law and the relationship between saving and investment. The parable also can be looked at as a demonstration of the neutrality of money wages as brought out in Keynes’s General Theory, in which...
money wages follow falling prices so that the real wage remains relatively unchanged. The importance of this parable and the way in which it led Keynes to his views in the General Theory on the consumption function and the principle of effective demand is explained by Ingo Barrens (1989).

The parable also provides insights into the debate between Friedrich Hayek and Keynes about the market economy. Hayek believed that market forces always align saving and investment in a smooth way unless there are distortions in the markets caused primarily by monetary policy. Keynes saw the economic landscape quite differently, positing that monetary policy and credit creation are absolutely necessary to stabilize the relationship between saving and investment, as is brought out in the parable.

BANDURA, ALBERT

1925–

Considered by some to be the father of behavioral psychology, Albert Bandura was born on December 4, 1925, in Mundare, a small town in Alberta, Canada. As a teenager, Bandura decided to take a psychology course to fill a space in his high school schedule. The result was a love for the subject that extended through his college years. He received his PhD in 1952 from the University of Iowa.

Promoted to full professor at Stanford University in 1964, Bandura often attributed his motivation for research to his collaborations with researchers such as Jack Barchas and Craig Barr Taylor. The joint research allowed them to combine different expertise and laboratory resources. One outcome of these research efforts was the finding that people regulate their level of physiological arousal (i.e., hormonal release) through their belief in self-efficacy. Bandura’s contributions to personality theory and therapy incorporated a three-way interaction between the environment, behavior, and psychological processes at a time when dynamic systems theory had yet to be defined. Bandura focused on observational learning, or modeling, and he showed that children learn behavior through watching others. His most famous study, known as the Bobo dolls study, established that children do not need punishment or reward to learn. With his then doctoral student Richard Walters, Bandura found that hyperaggressive adolescents often had parents who modeled hostile attitudes; the results led to Bandura’s first book, Adolescent Development (1959).

Bandura’s decision to relabel his theoretical approach from social learning to social cognition was due to his growing belief that the breadth of his theorizing and research had expanded beyond the scope of the social learning label. Bandura presented a social cognitive vision of the origins of human thought and action and the influential role of self-referential processes to motivation, affect, and action. He depicted people as self-organizing, proactive, self-reflective, and self-regulative in thought and action, rather than as merely reactive to social environmental or inner cognitive-affective forces. A major focus of Bandura’s theorizing addressed the extraordinary ability of humans to use imagery and symbolism. Drawing on their symbolic capabilities, people can comprehend their environment, construct guides for action, solve problems cognitively, support forethoughtful courses of action, gain new knowledge by reflective thought, and communicate with others at any distance in time and space. By symbolizing their experiences, people give structure, meaning, and continuity to their lives.

A further distinctive feature of social cognitive theory that Bandura singles out for special attention is the capacity for self-directedness as well as forethought. People plan courses of action, anticipate their likely consequences, and set goals and challenges for themselves to motivate, guide, and regulate their activities. The focus that Bandura gave to self-efficacy brought the term into mainstream conversation. Social learning theory is a general theory of human behavior, but Bandura and people concerned with mass communication have used it specifically to explain media effects. Bandura warned that children and adults acquire attitudes, emotional responses, and new styles of conduct through filmed and televised modeling. Bandura’s warn-
ing struck a responsive chord in parents and educators who feared that escalating violence on television and other forms of media would transform children into bullies. Although Bandura does not think this will happen without the tacit approval of those who supervise the children, he regards anxiety over televised violence as legitimate. That stance caused him to be blackballed by network officials from taking part in the 1972 Surgeon General's Report on Violence. The psychologist Kevin Durkin, who reviewed the research on violent video games in 1995, reported that studies had found “either no or minimal effects.” Indeed, he added, “some very tentative evidence indicates that aggressive game play may be cathartic (promote the release of aggressive tensions) for some individuals” (Durkin 1995, p. 2). Durkin and Kate Aisbett reported in a 1999 follow-up survey that “early fears of pervasively negative effects” from video games “are not supported”; “several well designed studies conducted by proponents of the theory that computer games would promote aggression in the young have found no such effects” (Durkin and Aisbett 1999, p. 3). These findings were echoed by other scholars.

To combat public policy problems, Bandura presided over the founding of the Association for the Advancement of Psychology as an advocacy group for promoting the influence of psychology in public policy initiatives and congressional legislation. He was elected to the presidencies of the American Psychological Association in 1974 and the Western Psychological Association in 1981. He was also appointed honorary president of the Canadian Psychological Association. In August 1999 Bandura received the Thorndike Award for Distinguished Contributions of Psychology to Education from the American Psychological Association (APA). In 2001 he received the Lifetime Achievement Award from the Association for the Advancement of Behavior Therapy. In August 2004 he received the APA’s Outstanding Lifetime Contribution to Psychology Award. He has written seven books and edited two others, which have been translated into numerous languages.

BANKING

Banking is the name given to the activities of banks. The word bank is derived from the Italian banca, which means bench. Moneylenders in Northern Italy originally did business in open rooms or areas, with each lender working from his own bench or table. In the modern era banks are financial firms that simultaneously issue deposits, make loans, and create money.

A deposit is issued when a household or a business brings cash or currency to a bank in exchange for an equivalent amount of stored value, which can either be used to meet payment obligations or saved for future expenditure needs. Loan making is a form of credit. Credit comes into being when one economic unit (the creditor) authorizes another (the debtor) to acquire goods prior to paying for the goods received. A bank makes a loan when it authorizes a borrower to make expenditures on the bank’s account up to a contractually agreed maximum level, in exchange for repayment of these advances later in time. Loans are usually made for expenditure purposes that are agreed on in advance (for example, the purchase of housing or of education services). Borrowers are normally authorized to use loan funds for a certain period of time and are required to repay the amount of the loan plus some amount of interest, which reflects the cost of the loaned funds. Common types of loans are working-capital loans, used by businesses primarily for buying supplies and making wage payments, and mortgage loans, which provide long-term funds (often for a duration of thirty years) for purchasing residences.

There are two principal types of bank deposits. Demand deposits are used primarily to handle transaction needs. They are completely liquid, as they can be withdrawn at will and without notice by the deposit holder. Time deposits are used primarily to store savings. They are less liquid than demand deposits, as they are normally contracted for fixed time periods (often six months or one year). In compensation for this loss of liquidity, those holding time deposits receive compensation in the form of (higher) interest payments.

The process of making loans may create money. A financial institution creates money in making loans when it creates demand deposits that can be spent by its borrow-
Banking Industry

The recurring problems in loan markets have made banking behavior a central topic in economic research. One key question is why lending booms and busts occur; another is why borrowers default (that is, are unable to repay loans according to their contractual obligations). Economists focusing on the first question have emphasized that banks are driven by competition to overlend in boom periods, leading to rising financial fragility (more debt obligations relative to available income), which eventually triggers a downturn (Minsky 1982). Economists addressing the second question focus on the distribution of information in credit markets; they emphasize that borrowers may seek to cheat lenders, and that banks may not accurately determine which potential borrowers are competent and which are not (Freixas and Rochet 1997).

Banking has always been a heavily regulated field of activity. For one, banks typically require a bank charter issued by regulators. Moreover, every economy normally has a central bank, which attempts to control money and credit growth and which is responsible for rescuing the banking system in times of acute crisis. Regulation is especially important at the beginning of the twenty-first century, because banks' behavior in loan making has changed so much over time. From the 1930s to the 1960s, banks were relatively cautious. They made loans up the amount of their excess reserves, that is, the amount of currency on hand beyond that needed to meet its deposit customers' normal withdrawal demands. Over time, banks became more aggressive in finding funds to lend. Banks evolved the practice of liability management, in which they set targets for asset and loan growth and reach those targets by borrowing reserves, primarily from other banks in the interbank market.

Banks have also become more aggressive in loan making, as a result in part of their deepening links to financial centers such as Fleet Street and Wall Street. Since the late 1970s, banks have competed to make loans in hot markets, including overseas borrowers. This has led to severe crises of loan repayment and refinancing, the most spectacular cases being the Latin American debt crisis of the 1980s and the East Asian financial crisis of 1997–1998 (Stiglitz 2003). Despite these recurring crises, banks continually push into new areas of loan making, searching for new ways to earn revenue. In the 1990s and 2000s, banks have increasingly extended personal credit (often via credit cards), and have gotten involved in such nonbanking activities as derivatives and options, mutual funds and insurance.

BANKING INDUSTRY

The modern banking industry is a network of financial institutions licensed by the state to supply banking services. The principal services offered relate to storing, transferring, extending credit against, or managing the risks associated with holding various forms of wealth. The precise bundle of financial services offered at any given time has varied considerably across institutions, across time, and across jurisdictions, evolving in step with changes in the regulation of the industry, the development of financial markets; Loans; Overlending

INTERNATIONAL ENCYCLOPEDIA OF THE SOCIAL SCIENCES, 2ND EDITION
Banking Industry

FUNCTIONS
Banks as financial intermediaries are party to a transfer of funds from the ultimate saver to the ultimate user of funds. Often, banks usefully alter the terms of the contractual arrangement as the funds move through the transfer process in a manner that supports and promotes economic activity. By issuing tradable claims (bank deposits) against itself, the bank can add a flexibility to the circulating media of exchange in a manner that enhances the performance of the payments system. These deposits may support the extension of personal credit to consumers (retail banking) or short-term credit to nonfinancial businesses (commercial banking). If so, the bank aids the management of liquidity, thus promoting household consumption and commerce. By facilitating the collection of funds from a large number of small savers, each for a short period, the bank promotes the pooling of funds to lend out in larger denominations for longer periods to those seeking to finance investment in larger capital projects. Financing investment may take the form of underwriting issues of securities (investment banking) or lending against real estate (mortgage banking). By specializing in the assessment of risk, the bank can monitor borrower performance; by diversifying across investment projects, the bank minimizes some types of risk and promotes the allocation of funds to those endeavours with the greatest economic potential. By extending trade credit internationally (merchant banking), the bank can facilitate international trade and commerce. As one last example, by lending to other banks in times of external pressures on liquidity, the bank can manage core liquidity in the financial system, thus potentially stabilizing prices and output (central banking).

To discharge its various functions, banks of all types manage highly leveraged portfolios of financial assets and liabilities. Some of the most crucial questions for the banking industry and state regulators center on questions of how best to manage the portfolio of deposit banks, given the vital role of these banks in extending commercial credit and enabling payments. With bank capital (roughly equal to the net value of its assets after deduction of its liabilities) but a small fraction of total assets, bank solvency is particularly vulnerable to credit risk, market risk, and liquidity risk. An increase in non-performing loans, a drop in the market price of assets, or a shortage of cash reserves that forces a distress sale of assets to meet depositors’ demand can each, if transpiring over a period of time too short for the bank to manage the losses, threaten bank solvency.

ORIGINS OF MODERN BANKING
The modern banking industry, offering a wide range of financial services, has a relatively recent history; elements of banking have been in existence for centuries, however. The idea of offering safe storage of wealth and extending credit to facilitate trade has its roots in the early practices of receiving deposits of objects of wealth (gold, cattle, and grain, for example), making loans, changing money from one currency to another, and testing coins for purity and weight.

The innovation of fractional reserve banking early in this history permitted greater profitability (with funds used to acquire income earning assets rather than held as idle cash reserves) but exposed the deposit bank to a unique risk when later paired with the requirement of converting deposits into currency on demand at par, since the demand at any particular moment may exceed actual reserves. Douglas Diamond and Philip Dybvig have, for example, shown in their 1983 article “Bank Runs, Liquidity, and Deposit Insurance” that in such an environment, a sufficiently large withdrawal of bank deposits can threaten bank liquidity, spark a fear of insolvency, and thus trigger a bank run.

Means of extending short-term credit to support trade and early risk-sharing arrangements afforded by such devices as marine insurance appear in medieval times. Italian moneychangers formed early currency markets in the twelfth century CE at cloth fairs that toured the Champagne and Brie regions of France. The bill of exchange, as a means of payment, was in use at this time as well.

Over the course of the seventeenth and eighteenth centuries, the industry transformed from a system composed of individual moneylenders financially supporting merchant trade and commerce, as well as royalty acquiring personal debt to finance colonial expansion, into a network of joint-stock banks with a national debt under the control and management of the state. The Bank of England, for example, as one of the oldest central banks, was a joint-stock bank initially owned by London’s commercial interests and had as its primary purpose the financing of the state’s imperial activities by taxation and the implementing of the permanent loan. This period was also marked by several experiments with bank notes (with John Law’s experiment in France in 1719–1720 among the most infamous) and the emergence of the check as simplified version of the bill of exchange.

Eighteenth-century British banking practices and structures were transported to North America and formed an integral part of the colonial economies from the outset. The first chartered bank was established in Philadelphia in 1781 and in Lower Canada in 1817. Experiments with free banking—as a largely unregulated business activity in
which commercial banks could issue their own bank notes and deposits, subject to a requirement that these be convertible into gold—have periodically received political support and have appeared briefly in modern Western financial history. Public interest in minimizing the risk of financial panics and either limiting or channelling financial power to some advantage has more often, however, dominated and justified enhanced industry regulation.

**BANK REGULATION**

Various forms of bank regulation include antitrust enforcement, asset restrictions, capital standards, conflict rules, disclosure rules, geographic and product line entry restrictions, interest rate ceilings, and investing and reporting requirements. The dominant view holds that enhanced regulation of this industry is necessary because there is clear public sector advantage, or for protecting the consumer by controlling abuses of financial power, or because there is a market failure in need of correction.

Where public sector advantage justifies the need for regulation, government intervention may appear in the form of reserve requirements imposed on deposit-taking institutions for facilitating the conduct of monetary policy or in the various ways in which governments steer credit to those sectors deemed important for some greater social purpose. Limiting concentration and controlling abuses of power and thus protecting the consumer have motivated such legislation as the American unit banking rules (whereby banks were limited physically to a single center of operation) and interest rate ceilings (ostensibly designed to prohibit excessive prices), as well as various reporting and disclosure requirements.

The latent threat of a financial crisis is an example of a market failure that regulation may correct. Here, the failure is in the market’s inability to properly assess and price risk. The systemic risk inherent in a bank collapse introduces social costs not accounted for in private sector decisions. The implication is that managers, when constructing their portfolios, will assume more risk than is socially desirable; hence, there exists a need for government-imposed constraint and control. State-sanctioned measures designed to minimize the threat of bank runs include the need for a lender of last resort function of the central bank to preserve system liquidity and the creation of a government-administered system of retail banking deposit insurance.

Regulation explicitly limiting the risk assumed by managers of banks includes restrictions that limit the types and amounts of assets an institution can acquire. A stock market crash will threaten solvency of all banks whose portfolios are linked to the declining equity values. Investment bank portfolios will be, in such a circumstance, adversely affected. The decline in the asset values of investment banks can spill over to deposit banks causing a banking crisis when the assets of deposit banks include marketable securities, as happened in the United States in the early 1930s.

The Bank Act of 1933 (the Glass-Steagall Act) in the United States as well as early versions of the Bank Act in Canada, for example, both prohibited commercial banks from acquiring ownership in nonfinancial companies, thus effectively excluding commercial banks from the investment banking activities of underwriting and trading in securities. This highly regulated and differentiated industry structure in twentieth-century North America contrasts sharply with the contemporaneous banking structures of Switzerland and Germany, for example, where the institutions known as universal banks offer a greater array of both commercial and investment banking services. The question for policymakers then is which industry structure best minimizes the risk of banking crises and better promotes macroeconomic stability and growth.

**BANKING AND MACROECONOMIC ACTIVITY**

The relationship between credit, bank notes, bank deposits, and macroeconomic stability has been the focus of much debate in the history of Western monetary thought. This debate grows more vigorous in the wake of financial panics and crises, when its focus turns to causality between banking crises and economic downturns.

Between 1929 and 1933 more than 40 percent of the American banks existing in 1929 failed. With no deposit insurance, bank failures wiped out savings and forced a severe contraction of the money supply. Milton Friedman and Anna Schwartz (1963) maintain that inaction by the American central bank permitted the sudden contraction of liquidity and magnification of real economic distress. Ben Bernanke (1983), too, believes that monetary conditions lead real economic activity, arguing that bank failures raise the cost of credit intermediation and therefore have an effect on the real economy. Charles Kindleberger (1986) alternatively suggests that non-monetary forces lie at the root of the problem, but that it was the failure of the Credit-Anstalt bank in Austria that proximately forced a sudden withdrawal of credit from the New York money markets and, in domino fashion, a contraction of credit throughout the United States. For Hyman Minsky (1982), the evolving margins of safety between the streams of asset income in relation to the contemporaneous changes in the cost of credit both characterize and explain financial instability.

Whichever the direction of primary causation, there is substantial agreement on the fact that there exists an important relationship between a sudden contraction of
credit and liquidity and a considerable decline in economic activity. Consensus arises also around the likelihood that central bank last resort lending, in the manner suggested by Henry Thornton (1802) or by Walter Bagehot (1873), had it been exercised, might have substantially mitigated these effects.

Despite being subjected to similar nonmonetary shocks, and despite existing in an economy that roughly mirrored the American economy at the time, the Canadian banking system of the 1930s proved itself less vulnerable to collapse. Two factors may explain the relative stability of the Canadian banking sector: a lower level of integration of commercial and investment banking activities and a much more highly concentrated industry, with only a few large banks dominating the Canadian banking landscape. While Richard Sylla (1969) suggests that monopolistic elements in the post-bellum U.S. banking industry were present and may explain the apparent inefficiencies he observes in the data, Michael Bordo, Hugh Rockoff, and Angela Redish (1994), for example, argue for an absence of evidence in support of any similar claim that Canadian bank cartels created gross differences in pricing. Contrary to common suspicion, stability, it appears, was not at the cost of any significant loss in efficiency, at least in the Canadian industry. Nevertheless, American apprehension about concentrations of financial power continued to prevail. Legislation designed to minimize the future possibility of such crises focused instead on enforced portfolio adjustments.

The relationship between crises and economic downturns has its counterpart in a later debate about the financial structure and economic growth. In broad strokes, as an economy develops in scale and scope, formal financial arrangements gradually (however incompletely) replace informal ones. As the economy’s need for larger amounts of funds to finance larger capital projects rises, the increasing inefficiency of many informal financial systems yields to the efficiency of formal codified transactions. As Rondo Cameron and Hugh Patrick (1967, p. 1) explain in Banking in the Early Stages of Industrialization, A Study in Comparative Economic History, the proliferation of the number and variety of financial institutions and a substantial rise in the ratio of money and other financial assets relative to total output and tangible wealth are “apparently universal characteristics of the process of economic development in market-oriented economies.”

In “Finance and Growth: Theory and Evidence” Ross Levine (2005, p. 867) examines the theory and evidence and concludes, “better functioning financial systems ease the external financing constraints that impede firm and industrial expansion, suggesting that this is one mechanism through which financial development matters for growth.” Whether the industry is segmented (with an enhanced role for capital markets) or not (as with universal banking systems, and their greater role for banks), does not seem to matter much, however. Several mutually reinforcing changes have stimulated a renewed public interest in this question about the preferred industrial structure.

POST-1980 INDUSTRY DEVELOPMENTS

The period from 1980 onward has been marked by increasing consolidation of banks, substantial loss in the share of financial activity to financial markets (disintermediation), greater market concentration, and considerable blurring of the traditional distinctions between banks and other financial institutions. Banks are increasingly offering a broader array of financial services in an increasing number of jurisdictions. The result is that banks in many countries where their scope was once limited are becoming more like universal banks.

Forces of change affecting the financial system since 1980 include market forces, legislative changes, and technological advances affecting communication and information. The dynamic tension and interplay between these forces have contributed significantly to the growth of new markets, new institutions, and new instruments, many of which fall outside the purview of existing regulation by virtue of their location or definition or both. The result is that an increasing amount of financial activity escapes regulation of any kind.

National responses have been largely to advocate and initiate deregulation of the domestic financial systems, justified by the same arguments that once supported the regulation. The elimination of interest rate ceilings, for example, should increase choice and competition, result in better and cheaper services for the customer, and increase the efficiency with which the economy allocates scarce funds. Permitting the integration of commercial and investment banking activities should produce greater efficiencies by permitting firms to capture greater economies of scale and scope. Notably, the legal separation of these activities was repealed in the United States with the 1999 Financial Services Modernization Act.

To date, international financial regulation is limited to the right-of-access rules negotiated by the European Union member states and by Canada, Mexico, and the United States, as part of the North American Free Trade Agreement, for example. Other international efforts have been largely and significantly restricted to international agreements to incorporate proposed rules into national legislation. The 1988 Basel Accord on the international convergence of capital measurements and standards, for example, recommended minimum common levels of capital for banks conducting international business. The twelve original signatories gradually adopted these capital
requirements, as did several other countries. The second Accord, reached in 2004, broadened the scope of the earlier agreement and increased its flexibility to meet the objective of setting standards for minimizing both credit and operational risks. There remain, however, several markets and instruments in the international arena that have yet to be regulated or at least have the relevant national regulation coordinated.

**FUTURE DIRECTIONS**

The future may well see an increased extent and variety of the bundling of financial services as techniques and technologies of securitization, networking, and outsourcing offer new organizational possibilities. The result thus far has been a blurring of the traditional distinctions between banking and non-banking financial activity. Bank mergers and mergers of banks with other financial firms are occurring with increasing frequency and magnitude, suggesting that the future may well witness both a greater dominance of universal banking structures and a greater international concentration of financial assets.

Perhaps more profound is the potential for the blurring of any clear distinction between financial and nonfinancial activities. Nonfinancial retailers are joining forces with banks or opening their own lending facilities outright. Developments in electronic communications and software have the potential to erode the banking industry’s relative monopoly over bank deposits as the nation’s dominant medium of exchange. It may only be a matter of time before the provision of commercial and retail credit already offered by some nonfinancial communications companies effectively challenges even these most traditional of banking activities. Whatever the precise institutional details—and they will continue to vary from jurisdiction to jurisdiction—the difference between financial and nonfinancial enterprises may be expected to become increasingly difficult to define and regulate as the banking industry continues to evolve.

**BARRIERS TO TRADE**

Barriers to trade include those made by policy and those posed by nature. Both policy barriers and natural barriers include several important types. Overall, despite much talk of globalization, barriers to trade of both types remain high (see Anderson and van Wincoop 2004 for a review of evidence).

**POLICY BARRIERS**

Policy barriers include tariffs and quotas. In past years and still in many countries, these have been substantial barriers to international trade. Tariffs and quotas discriminate in the treatment of goods between those produced at
home and those produced abroad. Other policy barriers can also be discriminatory.

Product standards, such as health and safety requirements, are on the surface nondiscriminatory. All autos sold in the United States must meet emissions standards. Under the surface, however, product standards are often used to discriminate. It is very difficult to make systematic evaluations of the effect of discrimination in product standards. Anecdotes abound, as in the notorious exclusion of Mexican trucking firms via discriminatory use of safety standards from the North American trade they are entitled to under the North American Free Trade Agreement.

The legal system’s treatment of aliens is often different than that of nationals, even though the laws themselves are mostly formally nondiscriminatory. Fair treatment of aliens is to some degree a policy choice. Again, anecdotes abound, but systematic evaluation of the effective policy discrimination is very difficult. Statistical inference that relates the pattern of bilateral trade to economic variables and to the quality of institutions (as measured by surveys of businessmen) suggests that bad-quality institutions harm international trade. For example, Anderson and van Wincoop (2004) report that Latin America’s institutional deficit relative to European norms reduces its imports by as much as Latin America’s tariffs.

NATURAL BARRIERS

Nature too imposes barriers to international trade. Most obviously, trade requires shipping, which increases in cost with distance. Distance reduces international trade relative to domestic trade because markets within nations are closer together on average than markets between nations. Transportation costs between most international markets are larger, usually much larger, than tariffs or tariff equivalents of quotas. Distance may also be associated with higher nontransportation trade costs, as it appears to reduce trade by more than can be accounted for by transportation.

Asymmetric information is another natural barrier to trade. Businessmen tend to know more about local markets than foreign markets. Information can be discovered at a cost, and this constitutes another trade cost. Statistical inference suggests that information costs can be large. Language differences, cultural differences, and institutional differences all reduce trade while ethnic ties increase it.

Attempts to infer the size of border barriers of all types give some idea of the size of barriers to trade. Inference can be done by comparing trade between regions of a single country with trade between regions in different countries, controlling for other influences, such as distance, on the size of trade. The average trade re- duction associated with crossing a border implies very substantial border barriers that are a large multiple of tariffs and the tariff equivalents of quotas (see Anderson and van Wincoop 2004 for detailed discussion).

BARRO-GROSSMAN MODEL

The Barro-Grossman model, proposed by Robert J. Barro and Herschel I. Grossman, was first published in 1971 in what was to become, seventeen years later, the most frequently cited article in the American Economic Review. It was further developed in Barro and Grossman’s Money, Employment, and Inflation (1976), though this latter work never became a dominant graduate textbook, as it was overtaken by what has been called the rational expectations revolution. Barro himself largely abandoned the Barro-Grossman model in the late 1970s. Though work based on the model continued to appear, and in that sense the model never disappeared, it was taught in very few graduate programs and fell out of fashion in the early 1980s.

The central idea of the model is that of an equilibrium with rationing, sometimes called the economics of disequilibrium. Suppose that for some reason—such as an external shock—an economy develops a significant level of unemployment. Workers will find that they cannot sell as much labor as they would normally expect to sell, and they will have to cut back on their purchases of consumption goods. Firms will find that they cannot sell the goods they wish to sell at the prevailing prices, and so will not be willing to employ more labor. The economy gets stuck in a “Catch 22” situation, in which spending cannot rise because workers cannot find jobs, even if they offer to work for a lower wage, and firms will not employ more workers, because even if they lower prices, they cannot increase their sales revenue. Both groups are rationed—that is, they face constraints on the quantities they can sell at the prevailing prices.

The key to the model is a distinction introduced by Robert Clower (1965) between effective and notional
demands, the former being calculated with quantity constraints taken into account, the latter with constraints ignored (notional demands are sometimes called Walrasian). In an equilibrium with rationing, effective demand equals supply. For example, workers may wish to sell more labor and purchase more consumption goods, but they cannot do so. Thus, if price changes depend on effective demands, there is no pressure to change prices. It is therefore possible to have an equilibrium with rationing in which there is high unemployment, even if wages and prices are at the level consistent with full employment. Market forces will not bring the economy back toward full-employment equilibrium.

The Barro-Grossman model was a fixed-price model in the sense that prices were taken as a parameter when determining quantities of employment and output. They were not necessarily constant—the 1976 version of the model allowed for inflation by having prices change in response to effective excess demands—but they adjusted much more slowly than quantities. In the late 1970s, Barro interpreted this as meaning that prices were fixed by long-term contracts, and when it was shown that it would not be optimal for such contracts to specify “sticky” prices (that is, prices that do not change immediately to eliminate potential differences between supply and demand), he abandoned the approach. However, other users of such models interpreted equilibrium with rationing differently. Clower had been interested in dynamic price-adjustment mechanisms in markets that were typically not perfectly competitive. Axel Leijonhufvud (1968), who had done more than anyone to popularize the idea of disequilibrium macroeconomics, was more interested in the idea of intertemporal disequilibrium. Jacques Drèze (1975), who pioneered the incorporation of quantity constraints in general equilibrium models, came to them through problems of information.

The folklore in macroeconomics is that the Barro-Grossman model went out of fashion in the 1970s because it did not make sense to assume rigid prices when inflation was running at levels that exceeded 25 percent in some OECD countries. However, paradoxically, it was precisely because of inflation that some economists turned to such models. Edmond Malinvaud (1977) used a model of equilibrium with rationing (not the Barro-Grossman model, but a member of the same family of models) because it was the only framework he could find in which to make sense of stagflation—that is, of simultaneously rising inflation and unemployment. Taking the wage rate and the price level as parameters was the first step in discussing what might cause an economy to move between different regimes: Keynesian unemployment (unemployment accompanied by a surplus of goods), classical unemployment (unemployment and a shortage of goods), and repressed inflation (shortages of labor and goods).

Possibly the main significance of the Barro-Grossman model in the history of macroeconomics is that it was an important part of the search for microfoundations of macroeconomics. Barro and Grossman wanted to construct a macroeconomic model with rigorous microeconomic foundations (rigorous in the sense of being based on maximizing behavior by individual firms and households). It should be seen as parallel to the search for microfoundations of Edmund Phelps and his collaborators (1970). Because macroeconomics was at that time synonymous with Keynesian economics, Barro and Grossman created a Keynesian model. Their model comprised a representative household and a representative firm. When Barro abandoned the fixed-price approach, he retained those elements, and when household and firm were combined, there emerged the representative agent model that is characteristic of modern macroeconomics.

**BATTLE OF ALGIERS, THE**

Often presented as an account of the Algerian struggle for freedom, Italian director Gillo Pontecorvo’s 1966 film *The Battle of Algiers (La battaglia di Algeri)* is in fact more precisely defined as an analysis of the strengths and limitations of counterguerrilla measures during the Algerian War (1954–1962) for independence from France and, as such, remains very relevant to the early twenty-first-century “global war on terror.” Though one of the major films of the 1960s, rightly rewarded with the top prize, the Lion of Saint Mark, at the Venice Film Festival in 1966, *The Battle of Algiers* is, in terms of its production, a marginalized film. Coproduced by Igor Films in Rome and shot in Algeria with an Italian crew, it is a key work of the Italian post-neorealist generation. Yet it is ignored (along with its director) in such standard English-language studies of Italian cinema as Millicent Marcus’s *Italian Film in the Light of Neorealism* (1986) and Pierre Sorlin’s *Italian National Cinema, 1896–1996* (1996). At the same time, it is self-evidently, with its Italian director, not part of Algerian national cinema, despite the major contribution of Yacef Saadi.

Saadi was the National Liberation Front (FLN) leader for the autonomous zone of Algiers, and it was his arrest by French General Jacques Massu on September 24, 1957, that brought to an end the Battle of Algiers, which had begun in January of that year with an eight-day general strike called by the FLN. Saadi’s book of memoirs, *Souvenirs de la bataille d’Alger* (Memories of the Battle of Algiers, 1962), is often cited as the source of the film (though it is not mentioned in the credits). Saadi also coproduced the film through his own company, Casbah Films, the only independent production company allowed to operate in postliberation Algeria, and he plays the role of the (fictional) insurgent leader, Djafar. But Saadi’s direct experience has been shaped into a knowingly constructed film narrative, which, far from offering the Algerian experience from within, presents instead a reflection on this experience from the outside perspective of two committed Italian Marxists, Gillo Pontecorvo and his regular scriptwriter, Franco Solinas.

The film begins at the end of a torture sequence, when the Algerian victim has been broken and has given the required information, and, for the opening credits, shifts smoothly into a French military raid over the roofs and through the alleyways of the casbah to the hiding place of Ali la Plante, the last FLN leader to remain at large. This opening sequence sets the tone and style of the entire film: grainy black-and-white photography and location shooting, but at the same time fast-paced, action-film editing and the emotive use of music. The film’s ambiguous attitude to the French torturers is apparent early in the film: they are men doing their job without personal animosity, and the colonel, their leader, is a man who tolerates no joking at the expense of the victim. Italian composer Ennio Morricone’s music for the French assault is jaunty and positive, echoing the music used for scenes of Italian partisan raids in neorealist films a decade and a half earlier. From a close-up of the trapped Ali’s face framed in darkness, there is a dissolve into a flashback to Algiers in 1954 and the start of Ali’s career.

Ali’s story is the conventional tale of a petty criminal who discovers his political awareness when he witnesses a prison execution. The film follows his rise within the FLN from impetuous newcomer to resourceful leader. His story is intercut with scenes of a trio of women who take on the key role of placing bombs in the French quarter of the city, which is ringed with barbed wire and accessible only through heavily guarded checkpoints, but is otherwise unsuspecting and unprepared. There is no attempt to minimize the horror of bomb attacks on defenseless men, women, and children or in any way to condone the French settlers’ revenge attacks, which occur with police connivance. The choice of Ali as protagonist—rather than the true leader and planner, Djafar—means that we never see the terror attacks as part of any coherent strategy, with thought-out objectives and tactics, on the part of the FLN. Within the film, the suffering of the Algerian people is depicted as leading “naturally” to the violence, so that the notoriously murderous internecine struggles within the FLN leadership are simply airbrushed out of the picture. Djafar is seen and heard only when he is a man on the run, aware that his very presence within the...
city brings danger to his followers. Thus the uprising in 
The Battle of Algiers is shown in narrative terms as an 
enigma: How is all this violence organized and how can it 
be stopped?

The man to resolve the enigma and deal with the 
stalemate of violence and counterviolence, Colonel 
Mathieu, makes his stirring entry into the film marching 
proudly at the head of his paratroopers past crowds of 
cheering settlers. Though we are notionally still within 
Ali’s flashback, it is Mathieu who is the driving force in 
the film from this point onward. His briefings to his 
troops are lessons in counterterrorism and his press con-
ferences present the justification for the use of torture by 
the French. If politicians will the outcome, they have to 
accept the necessary methods, however distasteful these 
may be. There is nothing personal about torture: it is just 
part of a job that has to be done. It is also Mathieu who 
lucidly points out—as the film takes on an increasingly 
didactic tone—that winning a battle is not the same as 
winning a war, and he goes to his next assignment “in the 
mountains” aware that none of his efforts can ultimately 
defeat a united Algerian people. His insights form a con-
text in which Ali’s choice of death rather than surrender 
can seem a fitting resolution to his personal story, while 
the audience can derive a wider emotional satisfaction 
from the spontaneous popular uprising in Algiers in 1960, 
which pressed the ending of French rule and with which 
the film concludes.

BATTLE OF THE LITTLE 
BIG HORN

The Battle of the Little Big Horn took place from June 25 
to June 27, 1876, along the river of the same name in 
what is now south-central Montana. The result is well 
known. Lakota Sioux, Northern Cheyenne, and a handful 
from other Northern Great Plains tribes defeated the 7th 
U.S. Cavalry regiment. The battle included several fights. 
In a separate engagement, the companies led by Major 
Marcus Reno (1834–1889; the regiment’s second-in-com-
mand) weathered a thirty-six-hour siege after warriors 
thwarted their attack on the Indian camp.

The Custer fight is historically the most visible event 
of the Little Big Horn affair. Shortly after Reno retreated, 
on a river bluff about four miles from Reno’s defense site, 
warriors wiped out to the man five companies (approximately 210 men) and their acting regimental commander, 
Lieutenant Colonel (Brevet Major General) George 
Armstrong Custer (1839–1876).

The event is indelibly fixed in the American social 
consciousness. It has been a symbol of bravery and spirit, 
of folly, and of oppression. This symbolism is largely a 
function of Custer’s presence. Its perception as folly, most 
visible during socially liberal times, is amply illustrated in 
the motion picture Little Big Man (1970; Dustin 
Hoffman, Faye Dunaway), and in various biographies, 
such as Frederic Van de Water’s Glory Hunter (1934), that 
portray Custer as an egotist willing to sacrifice others in 
his pursuit of glory.

Negative conceptions of the Battle of the Little Big 
Horn have their roots in the attitudes of Custer’s contem- 
poraries. Custer had achieved national prominence for his 
often daring (and usually highly successful) Civil War 
exploits (see Urwin’s Custer Victorious [1983]). With suc-
cess came jealousy, criticism, and accusations. Little Big 
Horn reinforced such views, ensuring their survival to this 
day. Conversely, the battle guaranteed Custer and his men 
symbolic immortality. At a time when the nation was cel-
brating its centennial, many Americans saw their deaths 
as noble sacrifices in the service of Manifest Destiny.

Promoters of Custer capitalized on these emotions, 
especially Custer’s widow, Elizabeth (née Bacon; 
1842–1933). Libbie (as Custer affectionately called her) 
ever remarried and spent the rest of her long life, as 
Shirley Leckie chronicles in Elizabeth Bacon Custer and the 
Making of a Myth (1993), carefully constructing the image 
of an heroic last stand—a steadfast fight to the final man 
against hopeless odds.

This image of the Battle of the Little Big Horn as a 
“last stand” has also been promoted by historians and 
Custer biographers. Charles Kuhlman’s Legend into 
History (1951) and Frederick Whittaker’s Complete Life of 
General George A. Custer (1876) are but two examples 
from a voluminous literature. Generally “last stand” sym-
bolism assumes prominence during socially conservative 
periods; the wartime film epic They Died with Their Boots 
On (1941; Errol Flynn, Olivia de Havilland) exemplifies
this. Here the doomed men fight bravely to the last man, in this case Custer himself.

Whatever the collective social mood of a given period, Custer’s “last stand”—as Brian Dippie argues in Custer's Last Stand: The Anatomy of an American Myth (1976)—has for the majority of Americans come to symbolize an indomitable American spirit. This is not the case in Native American circles. Rather, the Custer battle symbolizes triumph over oppression, perpetrated against not only Native Americans but also minorities in general (see Deloria’s Custer Died for Your Sins, 1969). Such symbolism is not confined to the Lakota and Cheyenne; it exists among Native Americans in general, and circulates widely among non-natives as well.

The symbolic value of the Battle of the Little Big Horn dwarfs its military importance. The battle, one of many during the Northern Plains Indian War Period (1862–1877), was a minor event. It had no influence on Indian policy, the foundations of which were formulated over two decades earlier. Nonetheless, followed as it was by the Army’s relentless winter campaign (1876/1877), it did indirectly hasten the surrender of Lakota and Northern Cheyenne bands (spring and summer of 1877). The defeated tribes were confined to reservation tracts, including the Great Sioux Reservation (originally the western half of present South Dakota, then reduced to small tracts in the Dakotas and Montana), established in 1868, and the Northern Cheyenne reserve (in south-central Montana), formed by Congress in 1884.

Custer the man permeates studies of the Little Big Horn battle, typically at great peril to objective analysis. Apologists are driven to absolve Custer of blame, most frequently by constructing events in ways that finger Major Reno. Like apologists, anti-Custer factions sometimes go to absurd lengths—but in order to blame Custer for the debacle, not one of his subalterns. Ultimately, the two sides find common ground in “last stand” imagery—whatever the chain of events, and whoever is blamed, Custer’s battalion fights to the end against impossible odds.

Only comparatively recently has the venerable notion of a “last stand” been challenged, by Douglas Scott, Richard Fox, and others in two books, Archaeological Insights into the Custer Battle (1987) and Archaeological Perspectives on the Battle of the Little Bighorn (1989). Using forensic analysis of firing pin marks on spent cartridges systematically recovered from the Custer battlefield, Fox shows in Archaeology, History, and Custer’s Last Battle (1993) that instead of mounting a resolute stand, Custer’s battalion fell apart. Cartridge case patterns show the command maintained tactical order (skirmish lines) initially, but subsequently lost cohesion. Denouement came amid panic and fear. Numerous eyewitness reports by Indian warriors support this interpretation. They speak of soldiers who “acted as if drunk,” “threw down their guns,” and so on. Native testimonies also indicate the end came in half an hour or so.

In the new synthesis, two independent lines of evidence—the material and documentary records—converge, providing interpretive confidence. Before the gathering of archaeological evidence, studies of the Battle of the Little Big Horn relied solely on highly contradictory historical documentation, which was easily manipulated in support of one or another preconceived notion of Custer and his men.

The historical-archaeological synthesis has not ended debate in Custer battle studies—but the case for a “last stand” is now far more difficult to argue. Authors who wish to keep this image of the battle alive—for example, Gregory Michno in Lakota Noon (1997)—are typically compelled to resort to special pleading, circular reasoning, revision, and selective use of evidence.

BAUMRIND, DIANA
1927–

Diana Baumrind’s seminal work on research ethics and parenting styles has shaped research and practice since the 1960s. Baumrind earned her undergraduate degree from Hunter College in 1948 and her PhD from the University of California, Berkeley, in 1955. Following a postdoctoral residency at Cowell Hospital, Baumrind joined the Institute of Human Development at the University of California, Berkeley, where she heads the Family Socialization and Developmental Competence Project as of 2007.

RESEARCH ETHICS
In response to Stanley Milgram’s 1963 study of obedience to authority, Baumrind published an influential commentary on research ethics (1964). Baumrind has continued to address ethical issues in research on humans through consultation with the American Psychological Association and published work. On the use of deception in research, Baumrind has emphasized multiple levels of potential harm: to the participant, to the credibility of psychology as a profession, and to society.

PARENTING STYLES
In 1966 Baumrind published a ground-breaking article on parenting styles, followed by a 1967 article with Allen Black examining the effects of parenting styles on girls’ and boys’ development. Baumrind’s three parenting styles involve different combinations of parental demand and control (confrontation, monitoring, consistent discipline, punishment) and responsiveness and affection (warmth, attachment, reciprocity, friendly discourse). Authoritative parents are moderately to highly demanding and highly responsive. Their children tend to be assertive, able to regulate themselves, socially responsible, and respectful to adults. Authoritarian parents are highly demanding and unresponsive to their children. Children of authoritarian parents tend to be moody, fearful of new situations, and low in self-esteem. Permissive parents are undemanding and nondirective. They are responsive to their children and avoid confrontation. Their children tend to be creative, sociable, and friendly, but may also be impulsive, aggressive, and resistant to limit setting. In 1983 Eleanor Maccoby and John Martin proposed a fourth style, uninvolved parenting. Uninvolved parents are undemanding and unresponsive, and their children may participate in deviant or high-risk behaviors.

Baumrind’s typology has formed the foundation for much research on parental socialization of children and children’s developmental outcomes. In her own work, Baumrind has examined parenting styles in parents of children of preschool age through adolescence. Outcomes that Baumrind has examined encompass academic achievement, emotion regulation, moral development, peer relations, social skills, substance abuse, and teenage sexuality. Baumrind has found authoritative parenting to be associated with better outcomes for children. This parenting style provides a model for children of care and concern for others’ needs and of confident and controlled behavior. Beginning in the late 1980s, researchers expanded Baumrind’s paradigm to families with low incomes and from diverse cultural backgrounds. Despite cultural differences in the degree of endorsement of different parenting styles and in the strength of the association of authoritative parenting with better outcomes in children, Baumrind’s typology has been largely supported.

More controversial has been Baumrind’s stance on physical punishment. While Baumrind argues that occasional, mild physical punishment may not lead to negative long-term outcomes in children when used as part of an overall authoritative parenting style, other researchers contend that parents’ greater use of physical punishment is associated with negative outcomes in children and that such use may escalate to physical abuse (Gershoff 2002b, p. 609). A point of agreement is that cultural norms regarding physical punishment influence the extent to which such punishment is perceived as harsh and is likely to have negative outcomes.

BAUXITE INDUSTRY

Bauxite is the only commercially viable ore used as a source material for primary aluminum production. After iron, aluminum is the world's second most used metal, having a wide variety of applications in transportation and packaging. Most of the world's bauxite reserves and production are found in a wide belt around the equator, with Australia, Brazil, Guinea, China, Jamaica, and India being the world's leading producers. While short-term demand for bauxite depends upon the demand for aluminum and is therefore cyclical, supplying countries have sufficient reserves to meet long-term projected demand for the foreseeable future.

The separation of primary aluminum from the other elements found in bauxite involves a distinct two-stage production process. First, 4 to 5 tons of bauxite is chemically refined into 2 tons of the white powder alumina (aluminum oxide), then these 2 tons of alumina are smelted into 1 ton of aluminum ingot. Both processes are highly capital intensive, and smelting is also highly electricity intensive. Of the bauxite mined worldwide, about 95 percent is converted to alumina; the remaining 5 percent is used in other applications such as abrasives and cement additives.

The world aluminum industry, from mining to fabrication, is both highly concentrated and vertically integrated. Multinational aluminum companies typically mine bauxite, which then feeds their alumina refinery operations, which then often feeds their own smelters. As a result, open markets do not generally exist for bauxite. Nearly all bauxite consumed in the United States is imported, mostly from Guinea and Jamaica.

Most of the world's bauxite reserves are found in developing countries, but these countries account for a much smaller percentage of world alumina production and very little of the world's aluminum production. Although bauxite and alumina production can typically play significant roles in terms of foreign exchange and gross domestic product in these economies, these capital-intensive production processes do not typically have significant macroemployment effects.

Nearly all of the world's bauxite is produced through opencast mining. This can have significant environmental effects, including detrimental effects on flora and fauna, water runoff resulting in groundwater contamination and soil erosion, and generation of dust affecting surrounding areas. The Third Bauxite Mine Rehabilitation Survey, published by the International Aluminum Institute in 2004, details these impacts and the progress that the industry has made at protection and reclamation.

Jamaica provides an example of the importance to the industry of a relatively small country and the key role that the industry plays in a supplying country's economy. Bauxite and alumina account for more than half of Jamaica's exports, and they are the country's second leading source of foreign exchange after tourism. The country's relationship with the industry has been historically confrontational. In the 1970s Jamaica was instrumental in forming an attempted bauxite cartel, the now defunct International Bauxite Association, while simultaneously but unilaterally implementing a domestic bauxite production levy. At the time, Jamaica was the world's leading producer of bauxite. After periods of industry stagnation and even contraction, the government changed approaches, and now directly participates in consortia with several of the world's leading aluminum companies in the country's bauxite and alumina operations. It has also replaced the bauxite levy with taxation on profits.

Two major issues face the industry: environmental impacts, and the desire by supplying countries to accrue a larger share of the benefits (income and employment) resulting from the downstream processing of their bauxite. The experiences of Jamaica and other countries have taught supplying countries and multinationals that direct equity participation in bauxite and alumina consortia by private or public supplying country partners is the most effective way to protect various stakeholders' interests.

James P. McCoy
Bay of Pigs

The Bay of Pigs invasion flowed from a directive signed by Republican President Dwight D. Eisenhower on March 17, 1960, authorizing the U.S. Central Intelligence Agency (CIA) to begin operations to remove the Castro government from power in Cuba (Kornbluh 1998, p. 269). This quickly evolved into a plan to land an invasion force of some 1,200 Cuban exiles near the city of Trinidad, Cuba, at the foot of the Escambray Mountains. The invasion force, called the Brigade 2506, trained in Central America and by the end of 1960 was making final preparations for the landing.

Meanwhile, however, presidential elections had been held in the United States. Vice President Richard Nixon, the Republican candidate, lost, and the Democratic candidate, Senator John F. Kennedy, won. The latter might have been expected to cancel the invasion plan, once informed of it, but this would have been difficult for him to do. During the election campaign, he had sharply criticized the Eisenhower-Nixon administration for allowing this Communist foothold to emerge only 90 miles to the south of the United States. Had he canceled the invasion, the Republicans would doubtless have gone public and pointed out that they had had a plan to remove the "foothold," but Kennedy had abandoned it.

Further, Kennedy quickly developed confidence in Richard Bissell (1910–1994), the CIA’s deputy director for plans, who was masterminding the operation (Wyden 1979, p. 96). Thus, Kennedy let the invasion plan go forward. He did insist, however, that a landing so near the city of Trinidad would be “too spectacular,” and requested that it be moved to a more remote location (Wyden 1979, p. 100). Bissell obligingly moved the site some 70 miles to the west, to the Bay of Pigs (Bahía de Cochinos). This meant, however, that if the invasion failed, the invaders could not melt away into the mountains and become guerrillas, as Bissell had suggested to Kennedy, for the mountains were now far away across impenetrable swamps (Wyden 1979, p. 102).

The invasion force of approximately 1,200 exiles seemed totally inadequate to the task at hand, given that they would face a regular army of 60,000 armed with Soviet tanks and artillery, and backed by a militia force of 100,000. Bissell assured Kennedy, however, that the invasion would spark a massive popular uprising against Fidel Castro. Unfortunately, this assurance was not based on any hard intelligence. Indeed, it turned out to be utterly baseless (Kornbluh 1998, p. 12).

Preparatory air strikes against Cuban airfields, flown by exile and CIA pilots operating from Central America, were quickly revealed to be exactly that and not strikes by defecting Cuban pilots, as the United States claimed.

Adlai Stevenson (1900–1965), the U.S. ambassador to the United Nations (UN), was deliberately misinformed by the White House, however, and gave a speech in the UN saying the raids had been carried out by defecting Cuban pilots. Outraged when he found out the truth, he complained to Kennedy, who ordered the next day’s air cover to be canceled. Nevertheless, as the CIA’s own report on the operation later stated, this was not “the chief cause of failure” (Kornbluh 1998, p. 12). The chief cause, rather, was the glaring disparity between the numbers of the invading force and the number of defenders. The former never really had a chance. They went ashore in the early morning hours of April 17, 1961, and by 2 p.m. of April 19, facing overwhelming odds, were forced to surrender. In retrospect, that surrender seemed so inevitable that the Bay of Pigs invasion came to be described as that rarest of all things—a perfect failure (Smith 1987, p. 70).

The failure of the United States at the Bay of Pigs had three crucial consequences. First, it solidified Castro in power. Second, seeing that if the United States used its own forces, he would need Soviet support to survive, to persuade Moscow to provide that support, Castro announced on April 16 that Cuba was a “socialist” state and he began to transform it into one, with a system patterned after the Soviet Union. And third, flowing in part from this transformation, Nikita Khrushchev the next year decided to place missiles in Cuba, thus leading to the October missile crisis of 1962.

Bay of Pigs: The Untold Story.

Bayes’ Theorem

With one posthumous publication on probability, Reverend Thomas Bayes inspired the development of a new approach to statistical inference known as Bayesian
Inference. “An Essay Toward Solving a Problem in the Doctrine of Chances” was published in 1764, but its impact was not felt until nearly two hundred years after his death, when in the 1950s Bayesian statistics began to flourish. His work remains at the center of one of the main intellectual controversies of our time.

Bayes was the first to solve the problem of inverse probability. In its simplest form, given two events A and B with nonzero probability, the probability of A and B can be written as:

\( \Pr(A \text{ and } B) = \Pr(A|B) \times \Pr(B) \) or \( \Pr(A \text{ and } B) = \Pr(B|A) \times \Pr(A) \)

Equating both right hand sides of (1) and (2) yields:

\( \Pr(A|B) = \frac{\Pr(B|A) \times \Pr(A)}{\Pr(B)} \)

In words, given the conditional probability of B given A, \( \Pr(B|A) \), one can obtain the reverse conditional probability of A given B, \( \Pr(A|B) \). For example, given that \( r \) heads out of \( n \) coin flips are observed, what is the probability of a head in a single coin flip? This allows one to work backwards, given the outcome or effect, to discover what is the probability of the cause. Viewed in this manner there is no controversy concerning Bayes’ theorem. It is a direct consequence of the laws of probability. However, viewing A as the parameters \( \theta \) and B as the sample \( D \) one obtains the following result from Bayes’ theorem:

\( \Pr(\theta|D) = \frac{\Pr(D|\theta) \times \Pr(\theta)}{\Pr(D)} \)

where \( \Pr(D|\theta) \) = posterior distribution of the parameters given the information in the sample

\( \Pr(\theta) \) = prior distribution of the parameters before the data is observed

and \( \Pr(D) \) = normalizing constant so that one obtains a proper posterior distribution.

In words, (4) states that:

\( \text{posterior distribution} \propto \text{likelihood } \times \text{prior distribution} \),

where \( \propto \) represents the relation “is proportional to.”

This relation is the foundation of Bayesian statistical inference, with the posterior distribution being the main component of statistical analysis. This provides a formal process of subjective learning from experience by showing how one can revise or update prior beliefs about parameters in the light of relevant sample evidence. The role of judgment or outside information in statistical modeling is made explicit in the Bayesian approach. The Bayesian approach views the parameters of the model as being random, and thus one can make meaningful probability statements about the parameters.

There are two major issues of contention in the Bayesian approach. The first is the subjective, or reasonable degree of belief, view of probability, which differs from the classical view of probability as the limit of the relative frequency of an event occurring in infinite trials. The second issue is the necessity and choice of an accurate prior distribution incorporating known information. The controversy over views of probability is a philosophical one that has yet to be resolved. Bayesians have suggested a wide variety of possible approaches for obtaining the prior distribution. The Bayesian approach requires more thought and effort, and thus the classical approach has a significant advantage in that it is much easier to apply in practice. The debate and interaction between these two contrasting approaches to statistical inference promises to lead to fruitful developments in statistical inference. Donald Gillies asks the interesting question, “Was Bayes a Bayesian?” and concludes, “Yes, he was a Bayesian, but a cautious and doubtful Bayesian” (1987, p. 328).

William Veloce

**BAYESIAN ECONOMETRICS**

Bayesian econometrics employs Bayesian methods for inference about economic questions using economic data. In the following, we briefly review these methods and their applications.

Suppose a data vector \( X = (X_1, \ldots, X_n) \) follows a distribution with a density function \( p_d(x|\theta) \) which is fully characterized by some parameter vector \( \theta = (\theta_1, \ldots, \theta_d) \). Suppose that the prior belief about \( \theta \) is characterized by a density \( p(\theta) \) defined over a parameter space \( \Theta \), a subset of a Euclidian space \( \mathbb{R}^d \). Using Bayes’s rule to incorporate the information provided by the data, we can form posterior beliefs about the parameter \( \theta \), characterized by the posterior density
Bayesian Econometrics

\[ p_\theta(X | \theta) = p_\theta(X | \theta) p(\theta) c, \]
\[ c = 1 / \int_\Theta p_\theta(X | \theta) p(\theta) d \theta. \]  
\[ (1) \]

The posterior density \( p_\theta(X | \theta) \), or simply \( p_\theta(\theta) \), describes how likely it is that a parameter value \( \theta \) has generated the observed data \( X \). We can use the posterior density to form optimal point estimates and optimal hypothesis tests. The notion of optimality is minimizing mean posterior loss, using various loss functions. For example, the posterior mean

\[ \hat{\theta} = \int_\Theta \theta p_\theta(\theta) d \theta, \]  
\[ (2) \]

is the point estimate that minimizes posterior mean squared loss. The posterior mode \( \theta^* \) is defined as the maximizer of the posterior density, and it is the decision that minimizes the posterior mean Dirac loss. When the prior density is flat, the posterior mode turns out to be the maximum likelihood estimator. The posterior quantiles characterize the posterior uncertainty about the parameter, and they can be used to form confidence regions for the parameters of interest (Bayesian credible regions). The posterior \( \alpha \)-quantile \( \theta(\alpha) \) for \( \theta_j \) (the \( j \)-th component of the parameter vector) is the number \( c \) such that \( \int_\Theta 1_{\theta_j \leq c} p_\theta(\theta) d \theta = \alpha. \)

Properties of Bayesian procedures in both large and small samples are as good as the properties of the procedures based on maximum likelihood. These properties have been developed by Pierre-Simon Laplace (1818), Peter Bickel and J. A. Yahav (1969), and Il’dar Ibragimov and R. Z. Has’minskii (1981), among others. With mild regularity conditions (which hold in many econometric applications), the properties include:

1. consistency and asymptotic normality of the point estimates, including asymptotic equivalence and efficiency of the posterior mean, mode, and median;
2. asymptotic normality of the posterior density;
3. asymptotically correct coverage of Bayesian confidence intervals; and
4. average risk optimality of Bayesian estimates in small and hence large samples.

The regularity conditions for properties (1) and (2) require that the true parameter \( \theta_0 \) is well identified and that the data’s density \( p_n(\theta_0) \) is sufficiently smooth in the parameters. Mathematically, property (1) means that

\[ \sqrt{n}(\hat{\theta} - \theta_0) \approx \sqrt{n}(\theta^* - \theta_0) \approx \sqrt{n}(\hat{\theta}(1/2) - \theta_0) \approx_d N(0, J^{-1}). \]  
\[ (3) \]

where \( J \) equals the information matrix

\[ -1/\int_\Theta \partial^2 \ln p_\theta(X | \theta_0) / \partial \theta \partial \theta', \]

\( \approx \) indicates agreement up to a stochastic term that approaches zero in large samples, and \( \approx_d N(0, J^{-1}) \) means “approximately distributed as a normal random vector with mean 0 and variance matrix \( J^{-1} \).”

These estimators are asymptotically efficient in the sense of having smallest variance \( J^{-1} \) in the class of asymptotically unbiased estimators. Property (2) is that \( p_\theta(\theta) \) is approximately equal to a normal density with mean \( \theta \) and variance \( J^{-1}/n \). Property (3) means that in large samples

\[ \text{Prob}(\hat{\theta}(\alpha / 2) \leq \theta_0 \leq \hat{\theta}(1 - \alpha / 2)) \approx 1 - \alpha. \]  
\[ (4) \]

In nonregular cases, such as in structural auction and search models, consistency and correct coverage properties also continue to hold (Chernozhukov and Hong 2004). Property (4) is implied by the defining property of the Bayes estimators that they minimize the posterior mean risk (Lehmann and Casella 1998). The property continues to hold in nonregular cases, which proved especially useful in nonregular econometric models (Hirano and Porter 2003; Chernozhukov and Hong 2004).

The explicit dependency of Bayesian estimates on the prior is both a virtue and a drawback. Priors allow us to incorporate information available from previous studies and various economic restrictions. When no prior information is available, diffuse priors can be used. Priors can have a large impact on inferential results in small samples, and in any other cases where the identifiability of parameters crucially relies on restrictions brought by the prior. In such cases, selection of priors requires a substantial care: See Gary Chamberlain and Guido Imbens (2003, 2004) for an example concerning simultaneous equations, and Harald Uhlig (2005) for an example dealing with sign restrictions in structural vector autoregressions. Conversely, priors should have little impact on the inferential results when the identifiability of parameters does not crucially rely on the prior and when sample sizes are large.

The appealing theoretical properties of Bayesian methods have been known for many years, but computational difficulties prevented their wide use. Closed-form solutions for estimators such as (2) have been derived only for very special cases. The recent emergence of Markov Chain Monte Carlo (MCMC) algorithms has diminished the computational challenge and made these methods attractive in a variety of practical applications; see for example, Christian Robert and George Casella (2004) and Jun Liu (2001). The idea of MCMC is to simulate a possibly dependent random sequence, \( (\theta^{(1)}, \ldots, \theta^{(B)}) \), called a chain, such that stationary density of the chain is the posterior density \( p_\theta(\theta) \). Then we approximate integrals such as (2) by the averages of the chain, that is, \( \hat{\theta} = \frac{1}{B} \sum_{b=1}^B \theta^{(b)} \).

For computation of posterior quantiles, we simply take...
The leading MCMC method is the Metropolis-Hastings (MH) algorithm, which includes, for example, the random walk algorithm with Gaussian increments generating the candidate points for the chain. Such random walk is characterized by an initial point \( \eta_0 \) and a one-step move that consists of drawing a point \( \eta \) according to a Gaussian distribution centered on the current point \( u \) with covariance matrix \( \sigma^2 I \), then moving to \( \eta \) with probability \( p = \min(\frac{p(\eta)}{p(u)}, 1) \) and staying at \( u \) with probability \( 1 - p \). The MH algorithm is often combined with the Gibbs sampler, where the latter updates components of \( \theta \) individually or in blocks. The Gibbs sampler can also speed up computation when the posterior for some components of \( \theta \) is available in a closed form. MCMC algorithms have been shown to be computationally efficient in a variety of cases.

The classical econometric applications of Bayesian methods mainly dealt with the classical linear regression model and the classical simultaneous equation model, which admitted closed-form solutions (Zellner 1966; Poirier 1995). The emergence of MCMC has enabled researchers to attack a variety of complex nonlinear problems. The recent examples of important problems that have been solved using Bayesian methods include:

1. discrete choice models (Albert and Chib 1993; Lancaster 2004); 
2. models with limited-dependent variables (Geweke 2005); 
3. nonlinear panel data models with individual heterogeneity (McCulloch and Rossi 1994; Lancaster 2004); 
4. structural vector autoregressions in macroeconomics, including models with sign restrictions (Uhlig 2005); 
5. dynamic discrete decision processes (Geweke, Keane, and Runkle 1997; Geweke 2005); 
6. dynamic stochastic equilibrium models (Smets and Wouters 2003; Del Negro and Schorfheide 2004); 
7. time series models in finance (Fiorentini, Sentana, and Shephard 2004; Johannes and Polson 2003); and 
8. unit root models (Sims and Uhlig 1991).

Econometric applications of the methods are rapidly expanding.

There are also recent developments that break away from the traditional parametric Bayesian paradigm. Jayanta Ghosh and R. V. Ramamoorthy (2003) developed and reviewed several nonparametric Bayesian methods. Chamberlain and Imbens (2003) developed Bayesian methods based on the multinomial framework of Thomas Ferguson (1973, 1974). In models with moment restrictions and no parametric likelihood available, Victor Chernozhukov and Han Hong (2003) proposed using an empirical likelihood function or a generalized method-of-moment criterion function in place of the unknown likelihood \( p_n(\theta) \) in equation (1). This permits the application of MCMC methods to a variety of moment condition models. As a result, there are a growing number of applications of the latter approach to nonlinear simultaneous equations, empirical game-theoretic models, risk forecasting, and asset-pricing models. The literature on both theoretical and practical aspects of various nonparametric Bayesian methods is rapidly expanding.

Bayesian Inference

Bayesian inference is a statistical method that allows for the updating of probabilities of hypotheses based on evidence, through the use of Bayes's theorem. This theorem, which is a cornerstone of Bayesian statistics, formalizes inductive reasoning and is often referred to as Bayes's theorem or Bayes's rule. The theorem is given by:

$$
p(H|E) = \frac{p(E|H) \cdot p(H)}{p(E)}
$$

where $p(H|E)$ is the posterior probability of hypothesis $H$ given evidence $E$, $p(E|H)$ is the likelihood of the evidence given the hypothesis, $p(H)$ is the prior probability of the hypothesis, and $p(E)$ is the marginal probability of the evidence.

Bayesian inference is concerned with the relationships among conditional and unconditional probabilities. Suppose the sampling space is a bag filled with twenty black and eighty white balls. The probability of a white ball being drawn at random is .8, as defined by the relative frequency of such balls. If three more bags with seventy black and thirty white balls each are in play and a ball is drawn at random from one bag, the probability of it being white is .8 · .25 + .3 · .75 = .425. Once a white ball is in evidence, the probability that it was drawn from the bag containing mostly white balls is larger than .25, and the probability that it was drawn from a bag containing mostly black balls is less than .75. The estimation of these inverse probabilities is the object of Bayes's theorem.

Let the idea that the obtained white ball came from the bag containing mostly white balls be $H$, for “hypothesis,” and the idea that the ball came from a bag containing mostly black balls be $\sim H$; let the drawing of a white ball be $E$, for “evidence.” Bayes's theorem states that

$$
p(H|E) = \frac{p(E|H) \cdot p(H)}{p(E)}
$$

or

$$
p(H|E) = \frac{p(E|H) \cdot p(H)}{p(E|H) \cdot p(H) + p(E|\sim H) \cdot p(\sim H)}
$$

which is .471. The ratio of $p(H|E)$ to $p(H)$ expresses the degree to which the probability of $H$ changes in light of the evidence. This degree of probability change can be seen before the posterior probability of $H$ is calculated because $p(H)$ is equal to the ratio $p(E)$, here 1.882.

The prior probability of a hypothesis constrains the degree to which it can be changed by evidence. If the evidence supports the hypothesis, the magnitude of the Bayesian revision decreases as the prior probability becomes larger. Consider the odds version of Bayes's theorem, which is

$$
p(H|E) = \frac{p(E|H) \cdot p(H)}{p(E|\sim H) \cdot p(\sim H)}
$$

Now, $p(H)$ becomes larger. Consider the odds version of Bayes's theorem, which is

$$
p(H|E) = \frac{p(E|H) \cdot p(H)}{p(E|\sim H) \cdot p(\sim H)}
$$

Note that a larger $p(H)$ reduces the second ratio, and thus reduces the product of the two ratios (where the first ratio > 1 if the evidence supports H). Analogously, a large $p(H)$ leads to a stronger updating if the evidence is contrary to $H$.

The Reverend Thomas Bayes (1702–1761) worked out his eponymous theorem, but his solution was only published two years posthumously (see Stigler 1999). The validity of the theorem is given by its mathematical coherence. Any of its constituent probabilities can be recovered if the others are known. As a model of scientific and of everyday inference, the theorem formalizes inductive reasoning. Scientists seek to corroborate or discredit certain hypotheses, and laypeople (and animals) need to mold their beliefs at least in part with reference to the observations they make. For inductive reasoning, not only the

**Bayesian Statistics**

Bayesian statistics is concerned with the relationships among conditional and unconditional probabilities. Suppose the sampling space is a bag filled with twenty black and eighty white balls. The probability of a white ball being drawn at random is .8, as defined by the relative frequency of such balls. If three more bags with seventy black and thirty white balls each are in play and a ball is drawn at random from one bag, the probability of it being white is .8 · .25 + .3 · .75 = .425. Once a white ball is in evidence, the probability that it was drawn from the bag containing mostly white balls is larger than .25, and the probability that it was drawn from a bag containing mostly black balls is less than .75. The estimation of these inverse probabilities is the object of Bayes's theorem.

Let the idea that the obtained white ball came from the bag containing mostly white balls be $H$, for “hypothesis,” and the idea that the ball came from a bag containing mostly black balls be $\sim H$; let the drawing of a white ball be $E$, for “evidence.” Bayes's theorem states that $p(H|E)$ is equal to $p(E|H)$, here 1.882.

The prior probability of a hypothesis constrains the degree to which it can be changed by evidence. If the evidence supports the hypothesis, the magnitude of the Bayesian revision decreases as the prior probability becomes larger. Consider the odds version of Bayes's theorem, which is $p(H|E) = p(E|H) \cdot p(H)$.

$$
p(H|E) = \frac{p(E|H) \cdot p(H)}{p(E|\sim H) \cdot p(\sim H)}
$$

Now, $p(H)$ becomes larger. Consider the odds version of Bayes's theorem, which is $p(H|E) = p(E|H) \cdot p(H)$.

Note that a larger $p(H)$ reduces the second ratio, and thus reduces the product of the two ratios (where the first ratio > 1 if the evidence supports H). Analogously, a large $p(H)$ leads to a stronger updating if the evidence is contrary to $H$.

The Reverend Thomas Bayes (1702–1761) worked out his eponymous theorem, but his solution was only published two years posthumously (see Stigler 1999). The validity of the theorem is given by its mathematical coherence. Any of its constituent probabilities can be recovered if the others are known. As a model of scientific and of everyday inference, the theorem formalizes inductive reasoning. Scientists seek to corroborate or discredit certain hypotheses, and laypeople (and animals) need to mold their beliefs at least in part with reference to the observations they make. For inductive reasoning, not only the
probable truth of certain beliefs is of interest, but also the probability that certain events will recur. In the previous example, the sampling of one white ball not only alters the probability that any particular bag was sampled, it also increases the probability that a white ball will be sampled again (assuming the next draw will be made from the same bag).

In the short run, the revision of the probability of the evidence may not reduce uncertainty. In the present example, where p(E) rises from .425 to .535, one would be slightly less confident to bet on any particular color for the next draw. Over repeated sampling, however, p(E) converges on either p(E|H) or on p(E|~H), and p(H) converges on 0 or 1. Prior uncertainty is greatest when there are many equiprobable hypotheses. If there were 101 bags, each with the different proportion of white balls, p(E) = .5. Pierre-Simon Laplace’s (1749–1827) rule of succession states that once a sample is drawn, the probability that the next draw (after replacement) will replicate the result is k + 1
n + 2, where k is the number of successes and n is the sample size. For an infinite number of hypotheses, this rule is obtained with integral calculus.

Bayesian alternatives to conventional hypothesis testing, confidence-interval estimation, meta-analysis, and regression are available, though computationally cumbersome. In practice, most researchers remain committed to orthodox methods that exclude prior knowledge. Fisherian null hypothesis significance testing, for example, yields the probability of the evidence under the null hypothesis, p(E|H). What the researcher really wants, namely p(H|E), cannot be estimated because, in the absence of p(E|H), the likelihood ratio remains undefined. If, however, the researcher specifies -H (as in the Neyman-Pearson approach) and assigns a probability to it, p(H|E) can be quantified. Indeed, prior probabilities can be represented as a distribution over possible outcomes. The mean of the posterior distribution is given by the weighted average of the prior mean and the empirical mean of the data, where the weights depend on the relative precision (i.e., the reciprocals of the variance of the means) of the prior mean and the mean of the data. Likewise, the standard deviation of the posterior distribution becomes smaller as the precision of the prior distribution or the distribution of the data increases (see Howard et al. [2000] for formulas and a numerical example).

Despite their reluctance to use Bayesian statistics for data analysis, many social and cognitive psychologists model the reasoning processes of their research participants along Bayesian lines (Krueger and Funder 2004). Any reasoning activities involving decisions, categorizations, or choices are natural candidates. Given some probative evidence, people need to decide, for example, if a person is male or female, guilty or innocent, healthy or sick. Likewise, they need to decide whether they should attribute a person’s behavior to dispositional or situational causes, and how much they should yield to a persuasive message. Even strategic choices between cooperation and defection in social dilemmas depend on what people assume others will do, given their own presumed choices.

The question of whether everyday reasoning satisfies Bayesian coherence remains controversial. In some contexts, such as jury deliberations, people appear to form their beliefs on the basis of narrative, not probabilistic, coherence. In other contexts, such as the Monty Hall problem, they fail to see how Bayes’s theorem can be readily applied. These difficulties can partly be overcome by altering the presentation of the problem. For example, diagnostic decisions in medicine are improved when the data are presented as frequencies instead of probabilities.

Many orthodox significance testers, who disavow the estimation of inverse probabilities, reveal implicit Bayesianism in their research practice. After a series of successful experiments, the probability of the null hypothesis being true becomes very small, and reasonable researchers desist from wasting further resources. The evidence of the past becomes the theory of the present, thus blurring the distinction between the two. Other hypotheses, such as the idea that a concerted mental concentration of a collective of people can alter the earth’s magnetic field, are so improbable a priori that even devout Fisherians would not consider testing them.

BEARD, CHARLES AND
MARY

The American historian Charles Austin Beard (1874–1948) in 1900 married Mary Ritter (1876–1958), a fellow Indiana-born DePauw student who became his lifelong intellectual companion and in her own right a pioneering historian of women. Mary followed Charles to Oxford University in 1900 and later enrolled for graduate work at Columbia University (1902), but pressures of child rearing and her growing involvement in Progressive community causes ended her work there. Charles Beard studied British legal institutions for his PhD in political science at Columbia, where he taught history (1904–1917); there he also wrote textbooks on European history with James Harvey Robinson and joined the New History movement to revitalize historical practice. Members of the New History movement, or Progressive historians, as they were also known, reoriented history toward solving current problems and integrated social, economic, and intellectual subjects into their political narratives. Beard was not only a Progressive but also a political activist seeking reform of government through the application of academic knowledge when he joined the New York Bureau of Municipal Research in 1914. Resigning from Columbia in protest over the dismissal of an antiwar colleague in 1917, Beard became increasingly dissatisfied with conventional academia as too intellectually conservative, and he helped to found the interdisciplinary and Progressive-oriented New School for Social Research (1919).

Though trained as an historian, Beard’s contribution straddled the porous borderland between the politics and history disciplines of the era. He wrote, among other works, *American Government and Politics* (1910), *American City Government* (1912), and *The Economic Basis of Politics* (1922). In 1927 he became president of the American Political Science Association, though historians continued to claim his allegiance, and he served as American Historical Association (AHA) president in 1933. Beard assumed a key role in the AHA’s attempted reform of high school history curricula as part of the Carnegie-funded Commission on the Social Studies in Schools (1929–1934). While working on the commission, he advocated in *A Charter for the Social Sciences in the Schools* (1932) the integration of the social sciences around Progressive history.

Beard was an avowed exponent of the economic interpretation of history as the study of interest groups, though he was not committed to class analysis in a Marxist sense. His controversial *An Economic Interpretation of the Constitution* (1913) examined the relationship of economics and politics at the Federal Convention of 1787, showing a clash of landed and mercantile property interests. His study of Treasury records revealed that those favoring the Federalist position held securities likely to be repaid if a federal government with a stronger financial basis were established; in a similar interpretive vein, he also wrote *Economic Origins of Jeffersonian Democracy* (1915). Empirical studies and a counter-Progressive trend in historiography eventually challenged his account of the Constitution, revealing a much more complex array of economic interests within the Federal Convention. His larger intellectual dominance faded by the 1950s, but in the meantime, he had influenced a generation of scholars from the 1920s. Increasingly he had become a public intellectual, reaching a wide audience through popular history books written with his wife.

Mary Beard not only served as a coworker, but also influenced his intellectual vision. She was herself an activist who worked in the suffrage and trade union movements before World War I. Seeing supposedly “objective” scientific history as biased because historians did not recognize women’s past contributions to human society, she stimulated Charles Beard’s relativist views. These later became a foundation for his presidential address to the AHA, “Written History as an Act of Faith,” which espoused political isolationism and attacked the foreign policy of Franklin Roosevelt in *President Roosevelt and the*...
Coming of the War: A Study in Appearances and Realities, 1941 (1948), but their legacy continued to influence the “consensus” historians of the 1950s, who tried to transcend the Beards’ work.

Beauty Contest Metaphor

John Maynard Keynes, in his famous chapter 12 of the General Theory of Employment, Interest, and Money (1936), wrote of the ways in which “enterprise” (the attentive study of fundamentals) would become less important to the workings of the stock market, and of the ways that “speculation” (predicting the psychology of the crowd under conditions of radical uncertainty) would increasingly determine market outcomes. In doing so, he likened speculation to a beauty contest run by a newspaper, where the winner is not the candidate that is the most beautiful (by some set standard), but the candidate that most people think is the most beautiful. If one wants to win, therefore, one does not choose the candidate one actually thinks is the most beautiful, but the candidate one thinks most other people will think is the most beautiful.

But there is a problem. As soon as one thinks this way, one imagines others may be thinking this way as well. One must then choose not the candidate one thinks most people think is the most beautiful, but the candidate one thinks most people think most people think is most beautiful. But as soon as one thinks this way, one again imagines others will think this way as well, and so on and so forth. This phenomenon, when agents consider not only their own forecasts but the forecasts of others and their forecasts of others, has been referred to as higher-order beliefs (Monnin 2004) or endogenous uncertainty (Kurz 1974).

It is easy to see how this approach can be used as a metaphor for the stock market. A trader is not interested, strictly speaking, in the “fundamentals” of a company, such as market outlook and technological capabilities, because if no one else buys that stock it really doesn’t matter. Its price will not rise. On the other hand, even if the fundamentals of a company do not look promising, if others believe that it is a good buy, for whatever reason, they will buy the stock and its price will rise. The lesson is not to buy the stock of a company one thinks is the best by some particular standard, but to buy the stock of a company one thinks others think is the best. But this soon leads to the same conundrum as occurs in the beauty contest, with the investor perpetually trying to stay one step ahead of everyone else. Keynes wrote that on a normal day this could expand to up to “four or five” iterations. In other words, a trader will be trying to anticipate what stocks on average “people think that people think that people think that people think that people think” are the best. At this point, values are completely separated from underlying fundamentals, and some of the best minds are engaged not in productive enterprise but guessing at mass psychology, subject to waves of optimism and pessimism, sometimes in response to phenomena difficult to get a handle on, or even to seemingly irrelevant factors. It has been shown, both theoretically and empirically, that such markets are highly volatile (see Monnin 2004).

BECKER, GARY S.
1930–
Born in Pottsville, Pennsylvania, Gary Becker obtained his undergraduate education at Princeton University. He did his graduate work in the economics department at the University of Chicago, where his interest in social issues was reinforced by the intellectual prowess and encouragement of his mentors, foremost Milton Friedman, but Gregg Lewis and T. W. Shultz as well. There he wrote his dissertation on the economics of discrimination in 1957.

After serving a few years as assistant professor, he moved to Columbia University in New York City, where he spent twelve years combining teaching with research at the National Bureau of Economic Research. During this period Becker produced perhaps his most influential work, Human Capital (1964), and published his seminal papers on fertility in 1960, the allocation of time in 1965, and crime and punishment in 1968. He returned to Chicago in 1969, where he produced his Treatise on the Family (1981, expanded in 1991), and has continued to develop his economic way of looking at behavior.

METHODOLOGY
Becker remains one of the most creative and influential economists in the early-twenty-first century. To characterize his vast theoretical contributions is a daunting task, which is helped by Becker’s own characterization of his work, as well as by attempts by others, including Sherwin Rosen, Agnar Sandmo, Ramon Febrero and Pedro Shwartz, and the Nobel Committee, to assess it. All recognize at least four areas of impact: discrimination, crime and punishment, human capital, and the family, to which should be added Becker’s work on economic growth. Another way to characterize Becker’s impact is by the methodological features that unite his work. For example, he applies the basic principle of rational behavior—preference maximization subject to objective opportunities or constraints—to all human behavior rather than merely behavior in the marketplace. Becker facilitates such applications by enriching the specification and interpretation of relevant opportunities and preferences, including explicit and implicit markets in which economic agents interact. He expanded both the opportunity set to incorporate time as a major scarce resource, and the structure of preferences to allow for material self-interest, as well as altruism, hate, discrimination, and moral values, emphasizing also the role of past experiences and social interactions in shaping these preferences.

Armed with these methodological innovations Becker expanded the boundaries of economics into areas that were traditionally the domain of sociology and political science. He pursues human behavior from cradle to old age, more or less in that order: discrimination, fertility, investment in human capital, time allocation, illegal behavior, self-protection, family behavior, politics, addiction, demographic change and economic growth, and social economics. More recently, Becker shifted his interest to health and aging issues.

MODELS: HUMAN CAPITAL, HUMAN BEHAVIOR, FAMILY BEHAVIOR
Another feature of Becker’s work is the formulation of models that produce empirically testable implications, in the tradition of Friedman’s positive economics. He explains variations in human behavior by focusing on the role of varying opportunities and market conditions rather than shifting tastes or deviations from rationality.

Becker’s work on discrimination was his first undertaking of an important social problem. By its economic definition, discrimination in the marketplace exists when employers, employees, or consumers are willing to incur costs in order to refrain from entering into transactions with other agents because of their race, gender, or religion. Such behavior yields private utility to those with a taste for discrimination but creates misallocation of resources and lowers economic efficiency. The theory explains not only why discrimination exists but also the variations in
its prevalence and impact on segregation and wage disparity over time and space based on varying production technologies, competition, population shares of the discriminating and discriminated groups, distribution of tastes for discrimination, government intervention, and economic growth.

The literature on human capital did not begin with Becker. However, he formulated and formalized the basic micro foundations and equilibrium analysis that transformed it into a theory of investment in various forms of human capital, wage differentials, and earning distribution. Becker's model, bolstered by the parallel development of Jacob Mincer's human-capital-earnings functions, has had a profound impact on the measurement of private and social rates of return to schooling and training and offered important insights concerning general and specific training, bonding between employers and employees, optimal wage contracts, and the sources of inequality in the distribution of labor income. The overarching importance of human capital has made the work relevant in virtually all areas of economic inquiry.

Crime and punishment was an area of inquiry of classical economists such as Cesare Beccaria, William Paley, and Jeremy Bentham, but Becker offered a systematic treatment of crime and public law enforcement, using optimization analysis and welfare theory. Taking offenders to be responsive to incentives, he applied the basic principles of rational behavior to specify their reaction to probability and severity of punishment. The main thrust of the work has been to derive propositions about optimal enforcement strategies concerning the balance between probability and severity of punishment, imprisonment and fines, compensations in civil litigations, and private enforcement, based on maximization of social income. Becker's work led to the development of a vast literature on the economics of crime, and influenced the law and economics movement.

Becker's fascination with the economics of the household and the family started with the economics of fertility and the allocation of time, and evolved into a wide range of family issues involving marriage, divorce, allocation of tasks within the family, parental altruism, inheritance, and investment in children, culminating in his expanded edition of A Treatise on the Family (1991). Becker also considered the long-term effects of human capital investments within the family. Following Robert Lucas's 1988 work on endogenous growth, in which human capital is identified as the engine of long-term sustainable growth of an infinitely lived agent, Becker and his colleagues offered a dynastic framework where altruistic parents make investments in children by partly trading off fertility and human capital investments. The work explains the process of development as a transition between stages of economic development, from a Malthusian Trap to a steady state of perpetual growth, over which period fertility declines.

**IMPACT BEYOND ECONOMICS**

Becker's influence transcends economics. At the outset, his work was met with skepticism and distrust, to some extent inside economics, as in Sandmo (1993), but mainly outside the profession where the controversy centered largely on the applicability of the rigorous economic methodology to complex social issues. Some even found the now universally established term human capital to be offensive, on the grounds that it likened humans to machines. Despite this, Becker persevered in his research and gradually gained wide acceptance among economists, as judged by the frequency with which his work is cited in, and augmented by, the research of others. Specific aspects of demography and health economics constitute one example, the economics of crime and law constitute another, and the literature on labor issues has been dominated by Becker's work on discrimination, time allocation within households, and human capital. But Becker also made inroads into other social sciences where sociologists and political scientists more frequently work with models based on rational choice. His belief in the widest applicability of economics as a social science links Becker, perhaps more than any other modern economist, with major classical economists who also adopted an all-embracing approach to social issues. His quest for a truly general science of society is continuing.

**Beggar-Thy-Neighbor**

**SECONDARY WORKS**

*Isaac Ehrlich*

**BEGGAR-THY-NEIGHBOR**

In economics, the term *beggar-thy-neighbor* describes economic policies that aim to enrich one country at the expense of other countries. Most commonly, the term *beggar-thy-neighbor* is used in relation to such international trade policies as the application of tariffs and other restrictions on imports, as well as currency devaluations that are intended to improve the international competitiveness of the goods the country is exporting. The policy is considered to be beggar-thy-neighbor when the welfare gain in the country imposing the policy is offset by the welfare loss in the countries affected by the policy.

Beggar-thy-neighbor trade policies could be aimed at protecting domestic industries that compete against imported goods. These policies may take the form of import quotas or import tariffs, both of which are aimed at restricting imports and also making them more expensive. For example, an import tariff will benefit the country because the tariff improves the nation's terms of trade. That is to say, by raising the price of imports the tariff causes the ratio of export prices to import prices to fall and thus makes the country's sales to others (exports) cheaper, while simultaneously making the price of purchases from its trading partners (imports) more expensive. Thus, an import tariff is a beggar-thy-neighbor policy (Feenstra 2004, chap. 7).

One of the roles of the World Trade Organization is to prevent such beggar-thy-neighbor trade policies. However, it should be noted that if import tariffs or currency devaluations are accompanied by other policy measures designed to increase economic growth in the country, they might not be beggar-thy-neighbor. The tariff, for example, will reduce imports but economic growth allows an increase of imports.

Currency devaluations are considered beggar-thy-neighbor if they are conducted solely for the purpose of boosting the country's exports by making them cheaper for foreigners to buy and therefore increasing the country's global market share. The trading partners of the country that undertakes a beggar-thy-neighbor devaluation may retaliate by devaluing their currency as well. Such a phenomenon, known as *competitive devaluation*, is an example of a beggar-thy-neighbor policy. Similarly, wage
repression policies could be beggar-thy-neighbor if their sole purpose is to increase a country's competitiveness in the international markets, which forces their competitors to repress wages as well.

During the Great Depression, the countries that were adhering to the gold standard, fixing the value of their currency to the value of gold, engaged in a series of competitive devaluations. In addition, many countries, including the United States, imposed protective import tariffs (the Smoot-Hawley Tariff Act of 1930 raised U.S. tariffs to historically high levels). Many economists have argued that such beggar-thy-neighbor policies worsened the economic decline during the Great Depression. Nevertheless, Barry Eichengreen showed that "competitive devaluations of the 1930s redistributed the Depression's effects across countries but did not worsen it overall" (1988, p. 90).

In July 1944 the delegates of forty-four countries met at the United Nations Monetary and Financial Conference at Bretton Woods, New Hampshire, and established the system of fixed exchange rates known as the Bretton Woods system. In addition, the conference instituted the International Monetary Fund and the World Bank. One of the purposes of the creation of these institutions was to avoid the return of the beggar-thy-neighbor policies of the 1930s.

In the early 2000s exports from China increased substantially. Some economists argue that such a fast increase can be partly attributed to the Chinese policy of keeping Chinese currency, the renminbi, at an artificially depreciated level in order to make exports from China very competitive. If this is the only reason the Chinese government keeps the value of the renminbi low, the policy could be classified as beggar-thy-neighbor.

Galina Hale

**BEHAVIOR, SELF-CONSTRAINED**

Self-imposed constraint or restraint has typically been defined in terms of willpower or other personal attributes assumed to be completely within the control of the individual, such as abstinence from pleasurable (sex) or unpleasurable (pain/illness) behaviors and conditions and the ability to cope with stress and dysfunction in one's life. For the vast majority of students of self-restraint, there are significant moral and social features of the behavior, and much research has attempted to address and even control these conditions. Featured below are some examples of what is known or believed about personal self-restraint from this research.

Research on self-restraint runs the gamut from the most basic (e.g., monitoring of food intake) to a middle range of investigations of control over sexual promiscuity or aggressive impulses, to the most serious forms of behavior, such as drug addiction or child abuse. Most research in food intake has addressed dieting behaviors and disorders, such as obesity or anorexia nervosa/bulimia, and these have largely been studied through genetics or other biological conditions. Much less work has been done on the most severe forms of problem restraint, with the exception of addictive disorders, where often an imprisoned or similarly institutionalized population is more readily available to be studied. The heaviest concentration of studies have been in the area in the middle, which tries to understand the triggers—personal, psychosocial, and environmental—that lead to initiation, maintenance of, or abstinence from risky or healthy behaviors. Most research links the problems to interventions to help solve them.

Additional work has addressed the efforts of individuals and their professional "helpers" to regulate their potentially excessive behavior. In the medical field, it is increasingly common for patients to ask their doctors to impose constraints by limiting or removing the opportunity for pain relief. For example, women who fear harmful side effects of anesthesia will preemptively insist that their doctors not administer drugs. Identified as "anticipatory self-command" and associated with rational choice theory, this behavior highlights the tension between individual preference and professional responsibility. The doctor is charged with minimizing discomfort and maximizing healthy outcomes. But it is, after all, not the doctor's body that is in question. In this case, both parties must or choose to administer self-constraints in order to ensure a desirable outcome. Lest this example seem isolated, think of how often people ask family or close friends to help them not do something, such as smoking ("you hold my cigarettes"), overspending ("hide my credit card from me"), or eating badly ("if you bring those into the house, don't tell me where they are"). Similar work has emphasized the need to acknowledge past behaviors and choices and build a present around this knowledge—that is, to constrain choices mostly by better understanding the self.

There is a vast literature about youth aggression and violence, much of it around sport, leisure, and play, which
tries to understand adolescent impulses toward healthy or risky behaviors. Generally researchers agree that a combination of personal factors, including gender and age, and social factors, including home/family environment, school setting, and peer relationships, affect youth participation in aggression/violence, delinquency, drug or alcohol use, sexual behavior, and the like. Studies show strong connections between personal qualities, such as a resilient personality, adaptive learning, and coping/resistance skills, and higher achievement in school, less problem behavior, and lifelong success. Many of these same studies show strong associations between social-environmental influences, such as strong bonds to healthy community institutions (e.g., school, family, neighborhood) and positive life outcomes. This research has led to a number of strong programs for youth that help build skills and strengthen the social environment, including Life Skills Training, All Stars, and Family Strengthening. Critical to the success of these programs is the skills building and environmental strengthening they combine with information sharing—information alone does not help and may actually hurt the people it is aimed at.

Another significant body of literature shows connections between personal (including DNA) and social-environmental forces and the most severe problem behaviors, such as eating disorders, HIV/AIDS, and drug addiction. Much of the genetic research that has been done on animals focuses on individual stimulus-response (Skinnerian) behaviors. For instance, scientists have been able to decrease desires for a substance (something as simple as sugar) by combining it with an unpleasant one (such as morphine). Many studies have shown that releasing addicts or criminals from prisons back to their unhealthy environments arouses the same “cravings” in them and is likely to lead to re-offending or re-abusing substances; some of these cravings can be controlled with “safe” stimulation and personal control practices that help internalize the value of abstinence. Research on dopamine, naturally produced by the body, suggests it can be regulated to affect drug and eating disorders and may hold a key to reducing problems of obesity and addiction. Similar studies point to the importance of serotonin, or seroconversion, in HIV/AIDS intravenous drug users. Even heavily individual and biological studies, however, point to the glut of social and environmental forces that are beyond the control of the individual and suggest the need to improve this environment. For instance, two cardinal features of human eating disorders are binge eating and body weight/body image, so understanding the social norms around a healthy body, controlling the availability of unhealthy eating patterns (e.g., “Supersize me”), and providing mechanisms to control behavioral and neurochemical abnormalities are critical.

BEHAVIORISM

Behaviorism is a twentieth-century term, made popular by the psychologist John Watson (1878–1958) in 1913. Although Watson introduced psychological behaviorism, there is also a version called philosophical behaviorism.

Psychological behaviorism is the view that psychology should study the behavior of individual organisms. Psychology should be defined not as the study of the mind and internal mental processes via introspection, but as the...
science of behavior. The most famous proponents of psychological behaviorism were John Watson and B. F. Skinner (1904–1990). Other notable behaviorists were Edwin Guthrie (1886–1959), Edward Tolman (1886–1959), Clark Hull (1884–1952), and Kenneth Spence (1907–1967).

**Philosophical behaviorism**, by contrast, is a research program advanced primarily by philosophers of the twentieth century. This school is much more difficult to characterize, but in general, it is concerned with the philosophy of mind, the meaning of mentalistic terms, how we learn this meaning, and how we know when to use these terms. Important philosophical behaviorists include Bertrand Russell (1872–1970), Gilbert Ryle (1900–1976), Ludwig Wittgenstein (1889–1951), Rudolf Carnap (1891–1970), Otto Neurath (1882–1945), Carl Hempel (1905–1997), and W. V. O. Quine (1908–2000). Other philosophers such as Daniel Dennett (b. 1942), Wilfrid Sellars (1912–1989), Donald Davidson (1917–2003), and Richard Rorty (b. 1931) have behavioristic sympathies to varying degrees.

Besides these two generic versions of behaviorism, there are several subvarieties (see Kitchener 1999; Zuriff 1985). **Eliminative behaviorism** is the denial that there are any mental states at all; there is just behavior. **Methodological behaviorism** is the view that it does not matter whether there is a mind or not; psychologists should just study behavior. **Logical behaviorism** (also called analytic behaviorism or semantic behaviorism) is the view that all mentalistic terms or concepts can be defined or translated into behavioral terms or concepts. **Epistemological behaviorism** and **evidential behaviorism** hold roughly the view that the only way to know about a mental state is by observing behavior.

**A BRIEF HISTORICAL OVERVIEW**

It should be noted that in the intellectual history of western culture there have been individuals who held views very similar to theories supported by one or both of these movements, even though they did not use the term behaviorism; others have championed views that may not be characterized as “behavioristic,” but which have had a strong impact on behavioristic ways of thinking (see Peters 1973–1974; Harrell and Harrison 1938). The writings of Aristotle (384 BCE–322 BCE), in particular his *De Anima*, his account of practical rationality in the *Nicomachean Ethics*, and his scientific work on animals (*De Motu Animalis*), contain ideas that were assimilated by later behaviorists. Likewise, the writings of the Stoics and the Skeptics contain several theoretical accounts that are sympathetic to a general behavioristic approach, especially their views about animal cognition.

Several seventeenth- and eighteenth-century works inspired behavioristic followers, including Thomas Hobbes’s generally mechanistic account of the mind, *The Leviathan* (1651), René Descartes’s 1637 account of animal behavior, *Discourse on Method*, and the writings of several individuals who belonged to the French Encyclopedists tradition of the Enlightenment, such as Julien de La Mettrie’s *Man a Machine* (1748), Pierre Cabanis’s *On the Relations between the Physical and the Moral Aspects of Man* (1802), and Baron d’Holbach’s *The System of Nature* (1770), among others.

**The Cartesian Tradition** A major philosophical issue emerging in the seventeenth and eighteenth centuries concerned the question of the nature of the human mind and the animal mind: Is it possible to provide a mechanistic, materialistic, and deterministic account of the human mind, or must one appeal to principles that are quite different from those used in modern physics? Descartes argued that the human mind is made of a substance different from any found in the natural world, one that operates by principles at odds with the ordinary causal processes of inorganic matter. Although humans possess this special kind of spiritual being, animals do not; they are, quite simply, machines that operate by ordinary “matter in motion” (Descartes 1637). Humans are radically different from such animals because the human mind is made of a quite different substance that is not observable by ordinary naturalistic methods; however, humans have a kind of special access to their own minds, found by means of internal reflection or introspection. None of this was true of animals, all of whose behavior can be explained mechanistically in terms of simple mechanical principles (see Rosenfeld 1941).

The question that arose, therefore, was this: If Descartes was correct about his animal psychology, was he also correct about human psychology? Do we need to appeal to a special nonmaterial substance to explain the behavior of humans, or can all of their behavior be explained in the same ways we explain animal behavior? Although Descartes’s answer was widely accepted, there were a few individuals who argued that humans are no different from animals, and hence if animal behavior can be explained along naturalistic lines—by observing their behavior and trying to explain it by deterministic laws of matter in motion—the same is true of humans. This was the view of some eighteenth-century thinkers who championed a purely naturalistic, materialistic, deterministic, and mechanistic account of humans. They were the forefathers of mainstream psychological behaviorism.

The nineteenth century produced philosophers and scientists who, in one form or another, contributed ideas that were fuel for the behaviorists’ fire. An example are the
Behaviorism

post-Kantian German idealistic philosophers, many of whom stressed the importance of praxis, or human action. These ideas in turn strongly influenced members of the philosophical/psychological school of pragmatism, including Charles Sanders Peirce (1839–1914), William James (1842–1910), and John Dewey (1859–1952). These pragmatists were concerned with understanding and providing an account of humans and animals that focused on their action—something that organisms did, something they tried to accomplish as they interacted in their physical and social environment. Strongly influenced by the Darwinian revolution, the pragmatists employed a Darwinian model of organisms adapting to their environments to understand action. Such an approach at once stressed the problem-solving nature of human and animal mentality and the assumption that everything that exists must be understood in a “functional” way—that is, how entities such as ideas are useful in an organism’s struggle to survive in its environment. All intelligence was to be explained in this way, as an “instrument of action.”

Although Sigmund Freud was no behaviorist, he did aid the behaviorist cause by challenging the reigning Cartesian model of the mind that maintained that humans had an immediate and privileged access to the inner workings of their minds that employed a first-person rather than a third-person perspective on the mind, and that tended to draw a sharp distinction between the human mind and the animal mind. Freud argued that the mind is not transparent to our internal gaze because most of our mental activity is going on below the surface at the level of the unconscious (Freud 1900). If this is correct, then the method of psychology cannot be assumed to be introspective. This opened the way to alternative methods of psychological investigation.

The work of Ivan Pavlov on the conditioned reflexes of dogs ([1927] 1960), as well as the work of other Russian physiological scientists, provided behaviorists with scientific accounts of behavior. Behavior occurs, persists, and changes as a result of classical conditioning: An original stimulus elicits some response; another stimulus is subsequently paired with the original stimulus, thereby acquiring the power to elicit the response. This version of S-R psychology is the paradigm for at least early behaviorism, providing an explanation of behavior. The other kind of learning employed by behaviorists was instrumental conditioning (operant conditioning, trial and error learning), first introduced in 1898 by Edward Thorndike (1874–1949). In instrumental conditioning, a response is learned because it is reinforced by a stimulus—the reward—where the response is instrumental in obtaining the reward. Classical and instrumental learning promised to explain all of behavior. None of this seemed to require private internal workings of a special kind of substance. Psychology could take its place among the objective natural sciences.

PSYCHOLOGICAL BEHAVIORISM

In psychology, behaviorism began with John Watson, who coined the term behaviorism and set forth its initial premises in his seminal article “Psychology as the Behaviorist Views It” (1913). Behaviorism, Watson suggested, should be considered an objective, natural science, one that studies the public, observable behavior of organisms. Rejecting the method of introspection practiced by his predecessors, Watson suggested a different method to be used by psychologists: Study the observable behavior of others, and to explain it, given the stimulus, predict the response; given the response, predict the stimulus. The aim of psychology, therefore, was the prediction and control of behavior. What then of the mind, that special substance that Descartes claimed was the special province of humans? Watson gave several different answers over the course of his career, including eliminative behaviorism, methodological behaviorism, and, later, the view that the mind exists but is the same as behavior. In short, Watson’s argument was this: Humans and animals are not radically different from each other, and since the behavior of animals can be explained without appealing to consciousness, the behavior of humans can be explained without appealing to consciousness, too. With the rise of the cognitive sciences in the 1960s, this conclusion was denied, and so was the claim that the behavior of animals can be explained without appealing to consciousness.

The key question is, what did Watson mean by “behavior”? Was it a mechanical physical movement of the body or something more complex—the intentional, purposive action of a rational agent? If the latter, then how can a purely mechanistic science account for it? This perplexing question remained at the center of discussion for decades. Doubts about a mechanistic approach gave impetus to versions of purposive behaviorism found in the writings of William McDougall (1912), Edwin Holt (1915), and E. C. Tolman (1932). Indeed, McDougall and Holt had been proposing a kind of teleological behaviorism before Watson had appeared on the scene.

We can divide the history of psychological behaviorism into several periods: (1) classical behaviorism, (2) neobehaviorism, (3) operant behaviorism, and (4) contemporary behaviorism. The first period (1912–1930) introduced the theory of behaviorism championed by John Watson and several other early advocates of behaviorism, including Max Meyer, Albert Weiss, Walter Hunter, and Karl Lashley. These behavioristic accounts were, by and large, naïve, sketchy, and inadequate, but they set forth the general program of psychological behaviorism.
The second period (1930–1950) was the era of neobehaviorism, so called because its philosophical underpinnings were somewhat different from its predecessors. Neobehaviorism was wedded to classical learning theory (see Koch 1959), and neobehaviorists were concerned with what form an adequate theory of learning should take. The main figures were Edwin Guthrie, Edward Tolman, Clark Hull, B. F. Skinner, and Kenneth Spence. All of these individuals spent a great deal of time laying out the philosophical bases of their respective kinds of behaviorism, and in doing so, they borrowed heavily from the school of logical positivism, which was influential at the time (but see Smith 1986). This resulted in an emphasis on the importance of operational definitions, a preference for a hypothetico-deductive model of theory construction, and a focus on issues about intervening variables versus hypothetical constructs, and the admissibility of neurological speculation. This move toward postulating internal mediating responses continued with later Hullian neobehaviorists such as Charles Osgood, Neal Miller, O. H. Mowrer, Frank Logan, and others.

The last two phases of behaviorism are more difficult to characterize. Skinner’s version of behaviorism—operant behaviorism—is markedly different from most of the other neobehaviorists, and yet he is perhaps the best-known behaviorist. Indeed, after the demise of Hullian learning theory in the 1960s, the main thrust of the movement switched to Skinner’s distinctive version of behaviorism.

Denying he was an S-R psychologist, Skinner championed an operant account of learning, in which a response that occurs is reinforced and its rate is increased (1938). The response—for example, a bar press or a key peck—is not elicited by any known stimulus, but once it has occurred, its rate of response can be changed by various kinds of reinforcement schedules. The response can also be brought under experimental control when it occurs in the presence of a discriminative stimulus (e.g., light). Such a relationship—discriminative stimulus, response, reinforcement—is sometimes called a contingency of reinforcement, and it holds a central place in Skinner’s brand of behaviorism. Skinner himself characterized his behaviorism as a “radical behaviorism” because rather than ignoring what is going on inside the organism, it insists that such events are still behavior (1974). However, such behavior still is caused by environmental variables.

Skinnerian behaviorism was the dominant version of behaviorism in the 1970s, and Skinner extended his approach to consider more and more complex behavior, including thought processes and language. His 1957 book *Verbal Behavior*, an example of this extrapolation, was reviewed by the linguist Noam Chomsky, who subjected it to devastating criticism (Chomsky 1959). Skinner declined to respond to Chomsky, and many individuals took this as a sign of the demise of behaviorism. This was not completely true, as can be seen in the current era of behaviorism, which features teleological behaviorism, interbehaviorism, empirical behaviorism, and so on (see O’Donohue and Kitchener 1999). Although behaviorism does not have the hegemony it once did, it continues to exist, but is restricted to pockets of research. Indeed, there are several scientific journals devoted to behaviorism, including the *Experimental Analysis of Behavior* and *Behavior and Philosophy*.

**Philosophical Behaviorism** Although psychological behaviorism can be described relatively clearly, philosophical behaviorism cannot. Fundamentally, a philosophical behaviorist is one who has a particular theory of the philosophical nature of the mind. All philosophical behaviorists are opposed to the Cartesian theory of mind: that the mind is a special kind of nonphysical substance that is essentially private, and introspection is the only or primary way of knowing about the contents of the mind, such that the individual has a privileged access to his mind. One or more of these tenets is denied by the philosophical behaviorist, who believes that there is nothing necessarily hidden about the mind: It is not essentially private, not made of a special substance, not known by any special method, and there is no privileged access to the mind.

In effect, the philosophical behaviorist claims that the mind is essentially something public, exemplified in one’s actions in the world, and that mentalistic properties are those displayed in certain kinds of public behavior. Such a view was championed by Bertrand Russell (1921, 1927; see Kitchener 2004). But what particularly distinguishes twentieth-century philosophical behaviorism is its commitment to *semantic behaviorism*, the view that philosophy is concerned with the analysis of mentalistic terms, concepts, and representations. This “linguistic turn” in philosophy (Rorty 1967) means that instead of talking about the nature of the mind as an object in the world, philosophers should be concerned with our linguistic representations of the mind. This type of philosophical behaviorism is called logical (analytic, conceptual) behaviorism. Philosophical behaviorism, therefore, is different from psychological behaviorism.

Ludwig Wittgenstein is sometimes called a behaviorist, largely because he was critical of the Cartesian model of the mind, especially its assumption that the meaning of a mentalistic term must be given in terms of one’s private sensations or states of consciousness. Such an account would amount to a private language because only the individual can know the meaning of a mentalistic term, an
item of his necessarily private experience. Private languages are not possible according to Wittgenstein, because any language must (initially) be a public language; the meaning of mentalistic terms must be intersubjective and public (1953). In order to use a word correctly, Wittgenstein claimed, there must be public criteria for its correct employment. Most individuals insist that Wittgenstein's kind of behaviorism is radically different from the psychological behaviorism of Watson and Hull. Whether it is fundamentally different from Skinner's behaviorism is still an open question.

Gilbert Ryle is also sometimes characterized as an analytic or logical behaviorist. Also rejecting the Cartesian conception of the mind, Ryle showed that mentalistic terms have to have public criteria for their correct use, and hence that mentalistic terms and states are not essentially private to the individual, but must be understood (largely) as complex behavioral dispositions, or actions (and tendencies to act) in certain kinds of physical and social situations (1949). According to Ryle, therefore, mentalistic terms are to be understood in the same way we understand the meaning of, for example, the term punctual. An individual is punctual if she shows up to class on time, regularly meets her appointments, and so on. Ryle had strong reservations about calling his views "behavioristic," largely because he thought behaviorism was committed to a mechanistic account of bodily movements and this was certainly not what behavior (or better, action) was.

As Ryle was influenced by Wittgenstein, so were other philosophical behaviorists. Rudolf Carnap and Carl Hempel were members of the group of philosophers known as logical positivists. According to a fundamental principle of logical positivism, the meaning of a statement consists of its method of verification. The meaning of a mentalistic term must be verifiable to be meaningful, and in principle, its meaning consists in how one verifies it by means of empirical observation. For example, the statement "Paul has a toothache" is (approximately) equivalent in meaning to the procedures one uses to verify that Paul has a toothache. Although this might consist in observing Paul's physical behavior, it might also consist in observing the state of Paul's tooth. Hence, for logical positivists, analytic behaviorism merged into the identity theory of mind and central state materialism—the view that mental states are central states of the brain. It remains unclear, therefore, to what extent they should be called "logical behaviorists"; certainly their version of logical behaviorism was quite different from Wittgenstein's and Ryle's.

The last notable philosophical behaviorist was Willard Quine, who was strongly influenced by Carnap (and Wittgenstein); nevertheless, his views are not easily assimilated with theirs. His views about meaning (and hence the meaning of mentalistic terms) were verificationist in spirit (because he was an epistemological behaviorist), but he did not share certain of Carnap's views about how to give a behavioral translation of mental terms. It cannot be done atomistically, but only holistically: One cannot give the meaning of single mentalistic term by giving observational conditions for its use. Indeed, Quine was suspicious of the very notion of "meaning" because such things, if they do exist, would be difficult to reconcile with naturalism and physicalism, and therefore the meaning of a mentalistic term cannot be equivalent to some item of behavior. Quine was also skeptical of the very possibility of verifying a statement by means of a set of observations; scientific observation is a much more theoretical affair than this. Nevertheless, Quine insisted that any science is committed to the observation of behavior (epistemological behaviorism, evidential behaviorism), and hence that mentalistic terms are, in some sense, equivalent to behavior. This is, in part, due to the public nature of language (Quine 1960). We obviously do learn what words mean in the process of learning a language, but all of this occurs in the public arena. We are taught how to use words by our linguistic community: In the presence of a public object such as snow, we learn (by principles such as those indicated by Skinner) to utter the word snow. Hence, Quine's behaviorism is sometimes called a linguistic behaviorism because he insisted that all we have to go on when we teach and learn a language is the public behavior of individuals. This is closely tied to the importance of empirical observation and verification. Furthermore, Quine was committed to semantic behaviorism, the view that the meaning of words is necessarily tied to (or consists of) public behavior. Meanings are, therefore, not "in the mind." This is a close cousin to the logical behaviorism of earlier philosophers.

With the rise of computer science and artificial intelligence in the 1960s, an interesting question arose concerning how one could decide if a machine such as a computer was intelligent or not (i.e., whether it "had a mind"). Alan Turing proposed a test—the "Turing test"—for deciding this question (Turing 1950). Basically, the Turing test holds that if you cannot distinguish a computer from a human in terms of its behavior, for example by asking them both questions and reading their answers, then because the human is intelligent, it would be difficult to deny that the machine is intelligent too.

The Turing test raises the issue of behaviorism once more, this time in the context of computers: Is it the actual behavior of the computer that is decisive in ascribing intelligence to it, or are the internal workings of the computer (e.g., using a lookup table) important? Those who answer yes to the latter question might be considered mentalists rather than behaviorists (Block 1981). There is reason to believe that Turing himself thought the internal
processing of the computer were important, something most behaviorists have never really denied.

**Objections to Behaviorism**

Psychological behaviorism and philosophical behaviorism have been criticized since the beginning of the twentieth century.

**Objection: Behaviorism Ignores or Denies Consciousness** Critics charge that because the behaviorist focuses on behavior—and this means external behavior—he or she ignores or dismisses the private internal realm of consciousness.

Let us assume that consciousness does exist, that individuals are aware of their internal mental thoughts and sensations. The methodological behaviorist argues that this realm can be ignored (from a scientific point of view) by simply refusing to consider it. Radical behaviorists argue that behaviorism does not have to ignore this realm; instead, one can simply treat consciousness as internal behavior not unlike the behavior of one’s stomach when it digests food. Or, a behaviorist might reply that consciousness is not actual occurrent internal behavior, but rather a behavioral disposition. This is what we ordinarily mean when we say things such as, for example, “the cat is awake and thinking about the mouse.”

One property of consciousness that it is particularly difficult for the behaviorist to accommodate are *qualia*—the internal “feel” of certain mental states or events, like the taste of chocolate or the feeling of a sharp pain. A related problem is how a behaviorist can handle images, for example, the image I have of my morning breakfast.

**Objection: Behaviorist Explanations Are Inadequate** Most behaviorists take behavior as that which needs to be explained—why it occurs, what its form consists of, why it ceases, and so on. But what provides the explanation of such behavior? The standard answer is that stimuli—external stimuli—provide explanations, together with psychological principles concerning the relation of such stimuli to responses. But according to the critic, it remains doubtful that external stimuli can provide such all-encompassing explanations. Instead, one must refer to certain kinds of internal states—typically cognitive states—to explain the behavior.

A very sketchy behaviorist reply would be that all explanatory internal states—including all “cognitive” states—can be explained in terms of the ordinary concepts of stimulus and response, as long as these terms are suitably modified. This typically has taken the form of saying that there are internal states occurring between the external stimulus and the external response but that these internal states are understood to be internal stimuli and internal responses; for example, according to Hull, internal states might be fractional anticipatory goal responses together with sensory feedback from them. These internal mediating mechanisms are not popular by contemporary cognitive standards, but if behaviorism is to be a viable research program, it must clearly postulate such an internal mechanism or something analogous. Whether these behavioristic models are sufficiently cognitive or representational remains an open question.

**Objection: The Behaviorist Concept of Behavior Is Inadequate** According to one popular argument (Hamlyn 1953), the behaviorist sees ordinary behavior as a mechanistic, physical response, like the movement of an arm. But this is an inadequate conception of human behavior, which is better thought of as an action, such as waving, signaling, flirting, or gesturing. The behaviorist cannot handle this kind of conception because actions are not mechanistic but rather intentional, teleological, rule-governed, governed by social norms, and so on, and these are incompatible with the behavioristic program.

The standard behaviorist reply is to deny the distinction between movements and actions and/or to argue that the behaviorist has always been interested in actions (Kitchener 1977), and that such a concept is consistent with a causal account.

**Objection: The Behaviorist Cannot Adequately “Analyze” or Define a Single Mentalistic Term by Means of a Set of Behaviors** Logical behaviorists attempted to translate a mentalistic term such as *belief* into a corresponding set of behaviors, for example, a verbal response. But such a translation is only plausible if we assume other mental states in our account, for example, other beliefs, desires, and so on. Hence we have not gotten rid of mentalistic terms (Chisholm 1957; Geach 1957) because there is no term-by-term reduction or elimination.

This objection carries little weight because logical behaviorists such as Carnap and Hempel very early in their careers gave up such a term-by-term approach in favor of a more holistic, theoretical approach, and this commands a central place in Quine’s holistic behaviorism.

**Objection: The Spartan Objection and the Dramaturgical Objection** A mental state, such as pain, is not equivalent to a set of public behaviors because it is possible for one to be stoic about pain: I might be in intense pain but never show it because, say, it is not “macho” to show pain. Likewise, I might manifest pain behavior but not really be in pain, as when I simulate pain as an actor in a play. Hence pain behavior is neither sufficient nor necessary for being in pain (Putnam 1975).
Both of these objections assume a very naive, “peripheral” behaviorism in which the behavior in question is publicly observable. It is necessarily restrictive because behaviorists can hold more sophisticated forms involving “internal” (covert) behavior along with the inclusion of behavioral “dispositions.” Secondly, the behaviorist has insisted that one learns the meaning of the term pain and to use the word correctly only in the context of public behavior, a view shared by Wittgenstein, Carnap, Quine, Sellars, and Skinner. There must be public criteria for the correct use of pain. So originally a certain kind of behaviorism must be correct; later, we may learn how to suppress such behavior and to internalize it. The basis of this claim concerns the learning of language and is based on Wittgenstein’s arguments against a private language, or on arguments similar to his.

CONCLUSION

Few individuals would claim that behaviorism today enjoys the popularity it once had. Indeed, many (or most) argue that behaviorism is dead—both in psychology and in philosophy. The claim is easier to make with respect to psychology, particularly in the aftermath of the cognitive revolution. Nevertheless, the reports of the death of behaviorism are somewhat exaggerated. Not only are there viable and interesting research programs that are behavioristic in name, there are signs that even in cognitive science and cognitive psychology there is a reemergence of behaviorism, for example, in connectionism (neural nets), robotics, and dynamic systems theory. In fact, according to some, it remains unclear how cognitive psychology differs from behaviorism, since most behaviorists have also been concerned with central cognitive states. Still, psychological behaviorism is currently a minor opinion.

In philosophy the matter is somewhat different. This is because of the centrality of language learning in analytic philosophy, which seems to demand something like a rule-following conception that presupposes a public or social conception of behavior. This view is shared by those sympathetic to Ryle, Wittgenstein, or Quine. The logical behaviorism of Carnap and Hempel is passé because it was abandoned early in favor of a central state theory of mind. But although psychological behaviorism may have seen its day, philosophical behavior, in one form or another, still claims the strong allegiance of many philosophers (depending on how one characterizes behaviorism).

**BENEDICT, RUTH**

1887–1948

One of the major figures in the development of American cultural anthropology, Ruth Benedict was educated at Vassar College (AB, 1909) and Columbia University (PhD, 1923), where she studied under the American anthropologist Franz Boas. Starting in the late nineteenth century, Boas and his students mounted an attack on social-evolutionary theories of human history. Boasian anthropologists showed that the evolutionists’ hypothesis of universal stages of development (“primitive,” “barbarian,” “civilized”) were belied by historical facts, especially by the diffusion of cultural materials and the movements of people. That people borrowed language and culture from one another meant that no group of people, and no
cultural whole or stage, had an identity that remained fixed over time. But this concept left open the question of what Benedict came to call “cultural integration.” Given that cultures were ceaselessly changing, how were anthropologists to talk about the coherence that people experienced in their life-worlds? Benedict’s two masterworks, Patterns of Culture (1934) and The Chrysanthemum and the Sword (1946), provide elegant answers to that question.

Benedict begins Patterns by pointing out that because the possibilities for a viable way of life are almost limitless, “selection” becomes a “prime necessity” of human history (p. 23). A group of people creates, borrows, and selects materials that it “integrates” into a consistent pattern, a cultural totality. In Benedict’s approach, the meaning of any item that has been incorporated into the whole depends upon its place within that whole; over time, disparate culture traits are woven together in a fundamental pattern such that any one of them can be understood only in terms of its relationship to all the others. Moreover, because cultural wholes are patterns of values in terms of which humans understand the world, people tend to understand (and misunderstand) other cultures by interpreting them in terms of their own. There is, therefore, a tension in Benedict’s anthropology between scientifically authoritative descriptions of integrated cultural patterns and ironic reflections on the way Western cultural values structure her readers’ (and her own) understandings of other cultures.

This tension is exemplified in Chrysanthemum, a book that came out of Benedict’s work analyzing cultures for the United States government during World War II. Chrysanthemum begins with a discussion of Japanese conceptions of hierarchy and indebtedness, for these contradict the crucial American values of equality and freedom. For example, because Japanese understand family relationships as grounded in indebtedness, they accept both filial and parental duties that to Americans seem overly severe and lacking in love. Similarly, civic duty in Japan is understood as repayment of debt to the supreme authority at the apex of the social hierarchy (the emperor). A person’s self-respect is bound to his fulfillment of such duties. By contrast, American self-respect depends on freedom, hence Americans tend to view governmental regulation as a violation of their dearest values—leading Japanese to find Americans to be lawless. Each culture misunderstands the other because apparently similar traits take on different significances in each.

As her study of Japan illustrates, Benedict believed that anthropology, by helping people to see their culture in a new light, could lead them to change customs that were no longer useful or humane. But such reforms were not to be imposed by force; rather, they should emerge, Benedict thought, from democratic discussion, both nationally and internationally. Benedict herself was willing to assert strong value judgments in her work, as, for example, in her critique of the obstacles women of her time and milieu experienced trying to balance family and career (a balance that was difficult for her to achieve, as her biographers make clear). Moreover, the work of Benedict and other anthropologists on the Japanese (carried out while Japanese Americans were being placed in internment camps) has come to seem problematic to historians and anthropologists who, since Vietnam, have become increasingly dubious that social science in the service of political power can promote democratic ends. Yet, as American difficulties in places like Iraq at the turn of the twenty-first century make clear, there is a place for the kind of anthropologically informed understanding of other cultures that Benedict did so much to advance. It is no surprise, therefore, that a New York Times essay on the rebuilding of Iraq concludes with the question, “Where are the new Ruth Benedicts?”

Ben-Gurion, David

1886–1973

David Ben-Gurion, along with Theodor Herzl (1860–1904) and Chaim Weizmann (1874–1952), is considered one of the three architects of Zionism and the most effective figure in founding the state of Israel. An early convert to Zionism, Ben-Gurion migrated to then Ottoman Palestine in 1906 at a point when the territory housed about 55,000 Jewish inhabitants—only about 1 percent of whom were Zionist pioneers—as opposed to nearly 700,000 Muslim and Christian Arabs. He devoted himself fully to organizing the Yishuv, or Jewish community, in Palestine prior to 1948 and to encouraging Jewish immigration to create a sufficient demographic basis for a Jewish state. In 1921 he became the secretary general of the Histadrut, the General Federation of (Jewish) Labor in Palestine, a position he retained until becoming the chairman of the Jewish Agency in 1935 before finally becom-
ing the first prime minister and minister of defense of Israel in 1948, positions he held, except for a brief period (1953–1955), until his retirement in 1963. After the creation of the State of Israel in 1948, Ben-Gurion adopted a more confrontational policy with Arab states than many of his compatriots in the leadership of labor, and his return to the cabinet in 1955 corresponded with preparations for the Sinai Campaign in 1956 in which Israel sought to invade Egypt in collaboration with Britain and France during the Suez crisis.

Ben-Gurion also played a key role in formulating a synthesis of labor ideology and Zionist nationalism, as evident in his early affiliation with P'Oalei Zion (Workers of Zion), which he represented during a three-year stay in the United States from 1915 to 1918, then the Mapai party and the Labor Party and as the first leader of the Histadrut. The Histadrut functioned as both a trade union and large employer in its own right, representing Jewish workers and creating Jewish economic enterprises. Its membership was exclusively Jewish, and it actively discouraged Jewish businesses from hiring non-Jewish inhabitants of Palestine. During the British Mandate period following World War I until 1948 when Palestine was administered by Britain, Ben-Gurion developed a working relation with the British administration, which allowed him to emerge as the face of the more “moderate” section of the Zionist movement at the same time that it facilitated his building of the paramilitary Haganah, which by 1948 had become the strongest and best organized military group in the land.

While far more pragmatic than other Zionist leaders, notably Ze'ev Jabotinsky (1880–1940) and, later, Menachem Begin (1913–1992), Ben-Gurion’s vision of Zionism made, in fact, little accommodation to the Palestinians. Throughout his life Ben-Gurion regarded the Arab Palestinians as economically, socially, and culturally inferior to the Jewish immigrants. Early in his career he believed that Arab Palestinians had no collective sense of nationalism and that a Jewish state could be built without infringing on them. He never accepted that they had political rights. Significantly, while he was versed in nine languages, he never made an effort to learn Arabic. Thus, in addition to being one of the greatest figures in the history of Zionism, he was also one of the main architects of an enduring conflict.

**BENIGN NEGLECT**

The concept of benign neglect was coined by the late Senator Daniel Patrick Moynihan (D-NY) in a January 1970 memo to President Richard M. Nixon while he served as the latter’s Urban Affairs counselor. The widely circulated memo, which was leaked to the press in March of that same year, read: “The time may have come when the issue of race could benefit from a period of ‘benign neglect’.” At that historical juncture, Moynihan declared, Americans needed “a period in which Negro progress continued and “racial rhetoric” faded. Moynihan believed that the antipoverty programs of the “Great Society” of the 1960s had failed miserably, not only because they had attempted to use money alone to solve the nation’s inability to properly educate the African American poor but also because they did not raise issues in reference to the viability of integration as a solution to U.S. racial problems. To most liberals—especially many civil rights leaders of the period—Moynihan had provided the rationalization for what Swedish political economist Gunnar Myrdal, in his classic *An American Dilemma* (1944), labeled a “laissez-faire” or “do-nothing” approach to racial problems. Most liberals at the time thought—and they thought correctly—that Moynihan’s concept was fatalistic—that is, that the intervention of the federal government on behalf of the African American could not alter the inexorable social forces that could only be assuaged by local initiatives. In short, the concept of benign neglect for all intents and purposes suggested that social programs that were endorsed and funded by the federal government created attitudes of dependency among the African American poor.

In contradistinction to Moynihan’s dire assessments, the recent research on antipoverty programs, conducted by such persons as Lisbeth B. Schorr, Daniel Schorr, Phoebe Cottingham, David T. Ellwood, James Comer, and many others, which were based on substantive, empirically verifiable data, demonstrated that social programs, when properly planned and executed, succeeded in reducing infant mortality and the incidence of low birth weight. Furthermore, programs such as Head Start and Job Corps succeeded in helping to remedy such problems as chronic unemployment and poor school achievement; and aided in the prevention of teenage pregnancy. The aforementioned programs, which had their origins in Lyndon B. Johnson’s Great Society initiatives, helped
many African Americans break the cycle of disadvantage. In essence, the concept of benign neglect, which was not based on empirical reality, ultimately blamed the victim and thus ignored the effects of the flawed structure of society in this nation.

Nevertheless, there has been a recent revival of the benign neglect arguments, which resulted in the 1996 welfare reforms and the introduction of the rhetoric of a “compassionate conservatism” into the presidential campaign of 2000. Furthermore, conservative black politicians and spokespersons have promulgated variants of the concept, which rationalized a terribly flawed social system.

BENJAMIN, JUDAH P. 1811–1884

Judah P. Benjamin, lawyer, U.S. senator, and Confederate official, was called “the dark prince of the Confederacy” and “the brains of the Confederacy.” Born in St. Thomas, Virgin Islands, a British subject, Benjamin achieved greater political power than any other Jew in the United States in the nineteenth century. His struggling Sephardic Jewish family settled in Charleston, South Carolina, in 1813. When Judah was fourteen, a wealthy Jewish merchant sponsored him at Yale University to study law. He mysteriously left after two years and in 1831 moved to New Orleans to begin his life as an apprenticed young lawyer. A strategic marriage to Natalie Martin, whose family belonged to the Catholic Creole aristocracy in New Orleans, and the 1834 publication of his book of reported Orleans and Louisiana Supreme Court decisions propelled him into financial success as an appellate lawyer, largely in commercial cases, and subsequently into a political career. But his wife humiliated Benjamin with her affairs and left him in 1845, in the midst of scandal, to move to Paris with their daughter.

In 1852 Benjamin was elected to the U.S. Senate. Before he was sworn in, he declined an offer from President Millard Fillmore for a seat on the U.S. Supreme Court. He was more interested in a political career. Soon Benjamin met Jefferson Davis (1808–1889), beginning a long friendship. With his reasoned and eloquent oratory, Benjamin became the most celebrated spokesman for the southern moderates. He was reluctant to leave the Union and favored compromise to head off war. He was quick to answer critics who attacked his religious background. “When my ancestors were receiving their Ten Commandments from the immediate Deity,” he said during a Senate debate on slavery, “the ancestors of my opponent were herding swine in the forests of Great Britain” (Kohler 1905, pp. 83–84). It was a rare reply. Usually when newspapers, political enemies, or military leaders ridiculed his Jewishness, he never answered but simply retained “a perpetual smile.”

After secession, Benjamin became attorney general of the Confederacy and Davis’s lieutenant and chief “implementer,” writing thousands of memoranda and orders and many speeches for the president. At times he seemed almost to be Davis and even was able to convene the cabinet and ask for a vote to give him constitutional authority to act in the president’s name, seeking presidential approval later. He was the only member of the cabinet without slaves, having sold his plantation with 140 slaves after his election to the Senate.

Soon promoted to secretary of war, Benjamin became the scapegoat when the war went badly and was bitterly attacked with anti-Semitic slurs—one newspaper referred to him as “Mr. Davis’s pet Jew” (Woodward 1981, p. 233)—and Confederate military officers groused publicly that he knew “as much about war as an Arab knows about the Sermon on the Mount” (Hunter 1905, p. 566). But Davis stood by him and made him secretary of state in 1862.

When the quick collapse of the Confederacy left Richmond in flames, Benjamin traveled south by train and then on horseback with the Confederate leadership. Soon he complained of saddle weariness and left Davis and his guard to escape in a broken-down horse and wagon, posing as a French doctor named “Monsieur Bonfals” (Cajun French for “a good disguise”). Sympathizers smuggled him to the Caribbean and then to London, as he fled the false accusation of involvement in the assassination of Abraham Lincoln.

Especially after the publication of his 1868 treatise on mercantile law, quickly known as “Benjamin on Sales,” Benjamin developed a flourishing law practice in international trade. He served in the House of Lords as a queen’s counsel, becoming familiar with the leading figures in English cultural and political life. Benjamin never spoke publicly about the war again and ignored charges that the fortune he built in England resulted from his escape with the Confederate gold.
After more than thirty years apart from his wife, Benjamin finally joined her in Paris in 1883. Benjamin died there on May 6, 1884, and was buried in Père Lachaise Cemetery with the great figures in French history.

Benjamin was the main beneficiary of the nineteenth-century emancipation of the Jews and its most visible symbol in the United States. Though he was a nonpracticing Jew, he never attempted to deny his faith, and his contemporary society treated him as Jewish. His election to the Senate was a watershed for American Jews, and because of the Civil War, he became the first Jewish figure to be projected into the national consciousness.

Benjamin has fascinated historians because of the extraordinary role he played in southern history and the ways Jews and non-Jews reacted to him. He remains as he always was—the prototype of the contradiction of the Jewish southerner, a stranger in the Confederate story.

BENTHAM, JEREMY

1748–1832

Jeremy Bentham, a philosopher and reformer, was born in London, entered Oxford University in 1760, and was admitted to the bar in 1769. Rather than practicing law, he devoted himself to its reform. His first major publication, A Fragment on Government (1776), attacked the jurist William Blackstone’s (1723–1780) Commentaries on the Laws of England (1765–1769) for failing to distinguish between description and criticism of the law and for adopting a nonexistent moral standard, the natural law.

Bentham argued that the only proper moral standard was the principle of utility, of which he gave his best-known exposition in An Introduction to the Principles of Morals and Legislation (printed 1780, published 1789). An action was morally right to the extent that it promoted the greatest happiness of the greatest number. Happiness consisted in a balance of pleasure over pain. The utilitarian legislator, by means of punishments and rewards, would encourage those actions that promoted happiness and discourage those that led to suffering.

The task of the legislator was to promote the “subends” of utility, namely subsistence, abundance, security, and equality. Security for person, property, reputation, and condition in life was essential for civilized existence, and, therefore, took priority. To promote equality at the expense of security of property would, for instance, prove counterproductive, since the disappointment of fixed expectations would produce pain in the individuals concerned, and ultimately threaten social stability. Nevertheless, Bentham recognized that inequality was in itself an evil, and he understood and applied the principle of diminishing marginal utility, advocating an equal distribution of resources so as to achieve without infringing security. Furthermore, in determining the utility of an action, the interests of each individual (irrespective of gender, religious beliefs, or social status) had to be given equal weight. From here, it was a short step to democracy, which Bentham first advocated in writings composed in 1788 and 1789 on the subject of the French Revolution (1789–1799). As the revolution became more extreme, Bentham, like most of his countrymen, became worried by the threat to social order and for many years put aside any consideration of political reform.

In the 1790s Bentham’s life was dominated by his attempt to build a panopticon prison in London. The panopticon consisted of a circular building, with the cells arranged around the circumference. The cells were thereby made visible at all times from a central inspection tower. The rejection of the scheme by the government in 1803 propelled Bentham into political radicalism. In writings on judicial evidence and procedure, he concluded that lawyers pursued their own selfish goals rather than the happiness of the community. In 1809 he began to extend this analysis to the political establishment, eventually calling for democratic reform in Plan of Parliamentary Reform (1817). He thereafter committed himself to republican-
ism, and concentrated on writing the *Constitutional Code* (1830), a blueprint for representative democracy.

Bentham's most sustained period of writing on economic questions took place from 1787 to 1804. The promotion of abundance, or the creation of wealth, which was both a security for subsistence and a source of pleasure in itself, was the subject of economic policy. In general, Bentham adhered to the free market principles associated with Adam Smith (1723–1790), on the grounds that individuals were the best judges of how to deploy their own resources. He also accepted Smith's principle that trade was limited by capital, arguing that there should be no prohibitions, bounties, or monopolies on foreign trade. There were, moreover, no economic advantages to the mother country in colony-holding, and those colonies able to govern themselves should be emancipated. Bentham advocated state interference in certain well-defined areas, including the provision of grain stores, encouragement of research, and dissemination of information. He was totally opposed to slavery and the slave trade, though he recognized that the abolition of the former would, in practice, require careful planning and execution.

Bentham's political thought, with its emphasis on the individual and democratic sovereignty, has contributed significantly to the development of liberalism. In economics, his notion of a calculation of utilities inspired the economist W. S. Jevons (1835–1882), and through him Alfred Marshall (1842–1924), in their development of the modern technique of cost-benefit analysis. Bentham's influence on the doctrines of classical economics is, however, less clear. His conception of economics was opposed both to the strand of political economy associated with Thomas Malthus (1766–1834), in that he rejected theology as an appropriate basis for legislation of any kind, and to the scientific strand associated with David Ricardo (1772–1823), in that he rejected the attempt to divorce economics from ethics. A proper assessment of Bentham's place in the history of economics will need to await the production of an authoritative collection of his writings on the subject.

When Bentham died, his body, following his instructions, was dissected for the benefit of anatomical research. His remains were then used to create the "auto-icon," the combination of skeleton, clothes, and wax head that is today displayed at University College London. The story that Bentham generally attends meetings of the College Council, and that the minutes record "Mr. Bentham present but not voting," is unfounded.

**BEQUESTS**

A bequest is the act of leaving personal wealth to a person or heir by a will. The distribution of bequests not only has potentially important consequences for the distribution of wealth but also the distribution of income. Bequests often take the form of income yielding assets, such as farms, businesses, rental property, financial assets, and more. The income from such assets is an important component of total household income, and the proportion of total household income from nonlabor sources increases as total income increases. In other words, high income households receive a higher proportion of their total income from non-labor sources than low income households. Thus, inequality in the distribution of bequests not only contributes to wealth inequality but income inequality as well.

The impact of bequests on the observed wealth inequality depends on the importance of bequests in total household wealth. If bequests are a large share of household wealth, then bequests may be an important factor in explaining the observed inequality in the distribution of wealth. And vice versa, if bequests are only a small share of household wealth, then the unequal distribution of bequests may play only a minor role in explaining the observed wealth inequality. Accordingly, considerable effort has been devoted to gauging the importance of bequests in household wealth. Economists Keiko Shimono and Hideaki Otsuki provide a review of the empirical evidence for Japan, the United Kingdom, and the United States in the early-twenty-first century. They report that the empirical evidence is mixed, with a wide range of estimates for each country. Generally speaking, some researchers find that bequests make up a large proportion of household wealth, with estimates as high as 80 percent; whereas others estimate that bequests are only a minor share, with estimates as low as 20 percent. The disparity in estimates for a given country derives mainly from the varying treatment of the interest income from bequests.

**EXPLAINING BEQUESTS**

In addition to gauging the potential effects of bequests on the distribution of household wealth, there are a variety of
theories in the economics literature attempting to explain what motivates individuals to leave bequests. In other words, why don’t people simply consume all of their wealth during their lifetime? A prominent explanation for bequest behavior is that parents may be altruistically motivated to save and thereby accumulate wealth in order to leave a bequest to their children and thus increase their children’s future happiness. This is often referred to as the bequest motive for saving. Formally, the parents’ utility or happiness may be a function of their children’s utility, and, in turn, each child’s utility is assumed to be a function of the bequest received from their parents.

Such theories can have interesting twists. The Samaritan’s dilemma, as explained by Ritsuko Futagami and his colleagues, describes a situation in which a child may save an inadequate amount of money in order to maximize the bequest from their parents, and the rotten kid theorem suggests that parents may give larger bequests to their delinquent or rotten children in order to elicit good behavior from them in the future. In any event, such theories suggest that the so-called bequest motive of saving may be an important explanation of household saving. As such, there is an extensive literature attempting to model the bequest motive as well as measure its importance in explaining household savings and the accumulation of wealth.

Mohamed Jellal and Francois-Charles Wolff find that parents who themselves are given bequests are more likely to give bequests to their children. As such any policy that affects current bequests to children may affect the bequest behavior of future generations. In this view, any program that currently affects the level of public taxes and subsidies will have a long-term impact on the provision of bequests due to habits passed on to them by the example set by their parents. In other words, parents who are net-beneficiaries of government programs will redistribute more resources to their children because they have higher incomes and the social safety-net provided by government programs reduces the need for precautionary bequests. In addition, by making a bequest, parents shape the preferences of their children, who in turn leave larger bequests to their own children.

**BEQUESTS AND PUBLIC POLICY**

Modeling the bequest motive is not merely of academic interest; the nature of the bequest motive also may have important implications for public policy. For example, according to the bequest motive of savings, a change in government tax or transfer programs may influence the future welfare of future generations. If parents care about the future happiness of their progeny, then households may adjust their savings behavior to leave a bequest which partially or fully offsets the anticipated change in government policy on the future welfare of their children, and, perhaps, their children’s children. For example, if parents and grandparents perceive that a government financed retirement program has made them better off at the expense of higher current or future taxes on their children and grandchildren, they may leave larger bequests in order to offset the deleterious effects of the program on their children and grandchildren’s welfare.

The bequest motive of savings also has important implications for the economic effects of inheritances taxes and government deficits. If parents save in order to leave a bequest, then changes in inheritances taxes may change their savings behavior because it changes the cost or net-of-tax price to the individual of a bequest of a given amount. More specifically, if the inheritance tax rate is 50 percent, then a $1.00 transfer net-of-taxes requires a $2.00 transfer. David Joulfaian traces the effects of income and estate and gift taxes on the net-of-tax price of wealth transfers. His estimates suggest that taxes may have a significant effect on the timing of transfers, which suggests that the wealthy are influenced by taxes in setting their lifetime transfers, adding another dimension to the literature on bequests.

Regarding the implications of bequests for government deficits, many economists maintain that deficit financing of government expenditures may result in higher interest rates and thereby crowd out private investment. If the return to private investment is higher than the return to public investment, then the crowding-out effect of deficits could be harmful to economic growth. According to Robert Barro a deficit-financed cut in current taxes leads to higher future taxes. Parents, however, may adjust their savings in order to leave larger bequests to their children in order to offset the effect of future tax liabilities on their children’s future income (wealth). In this case, there is no crowding-out effect from deficit financing because the future tax liabilities are offset by an increase in current savings; there is no change in the interest rate, and private investment is unaffected.

BERG, IVAR E.

1929–

Ivar Berg is a sociologist who has made important contributions to the study of education (especially higher education), labor markets and social stratification, human resources, managers and corporations, and industrial sociology generally. In more than a dozen well-known books and more than seventy articles and chapters, Berg has addressed a variety of scholarly issues related to these topics. He is best known for his pathbreaking study Education and Jobs: The Great Training Robbery (1970), which posed a significant challenge to conventional economic theory's treatment of human capital and income distribution.

Berg was born on January 3, 1929, in Brooklyn, New York, where he attended kindergarten through high school. His undergraduate education was interrupted twice by service in the U.S. Marine Corps: He was on active duty from 1946 to 1948 and 1950 to 1952, serving in infantry communications in the First and Second Marine Divisions (he resigned in 1965 at the rank of major). He obtained his AB with high honors in political science from Colgate University in 1954. Returning to his Norwegian roots, he was a National Woodrow Wilson fellow and a Fulbright scholar at the University of Oslo from 1954 to 1955. He did his doctoral work at Harvard University from 1955 to 1959, receiving his PhD in 1959 under the tutelage of Alex Inkeles.

He has been a member of the faculties of Columbia University and Vanderbilt University, where he was a professor of economics and sociology, and in the sociology department at the University of Pennsylvania. Toward the end of his sixteen-year-long stay at Columbia University he served as the associate dean of Columbia's fourteen faculties in an interim administration following the upheavals in 1968 related to the Vietnam War. Berg later chaired the University of Pennsylvania's Department of Sociology (1979–1983), and served as dean of Penn's College of Arts and Sciences from 1984 to 1989 and as dean of Social Sciences from 1989 to 1991. In 2001 he was awarded the University of Pennsylvania's Ira Abrams Award for Excellence in Undergraduate and Graduate Teaching. Berg is also a member of Phi Beta Kappa, and has been elected a Fellow of the American Association for the Advancement of Science, the New York Academy of Sciences, and the International Academy of Management.

Berg’s research focuses primarily on the relationship of education to work, as well as on the work structures (e.g., organizations, industries, unions, occupations) that characterize industrial societies. He has argued forcefully for the importance of studying the social bases of market phenomena, maintaining that analyses of social institutions and employers’ motivations are needed to supplement economists’ emphases on supply-side dynamics to understand labor market outcomes (Berg 1981). Moreover, Berg has consistently urged that it is essential to study work and its correlates at multiple levels of analysis (see Berg 1979; Kalleberg and Berg 1987). Explanations should include work structures and institutions operating at macroscopic (such as government policies and relations among nations in a world economy), mesoscopic (such as industry sectors and labor force developments), and microscopic (such as the job definitions and human resource practices that take place within organizations) levels of analysis.

Berg’s classic book Education and Jobs: The Great Training Robbery still exerts a profound impact upon the ways employers, academic leaders, and public policy makers have come to think about the linkages between education, personal development, income distribution, and employment. He argued that despite the claims of human capital theory in economics, peoples’ educational attainment does not always correspond to their skill levels. On the contrary, Berg’s analyses found evidence that employers frequently hire people with certain required levels of education to work in jobs that do not make use of their education (hence, the “great training robbery”), and that employees with more education are not necessarily more productive, and in some cases are actually less productive than workers with less education. Moreover, Berg’s results showed that the rise in educational requirements for jobs in the United States reflected primarily the increase in educational attainments of workers (and an emphasis on “credentials”), not the actual technical requirements of jobs.

Berg’s study cast doubt on economists’ assertions that people with more education earn more because they are more skilled and productive. It also cautioned against using educational credentials as indicators of skills, an insight that played a major role in a landmark civil rights decision by the U. S. Supreme Court, Griggs v. Duke Power Company (1971). Moreover, Berg’s notion of credentialism was credited with providing the bases of the formal theory of market signaling, for which George A. Akerlof, A. Michael Spence, and Joseph E. Stiglitz shared the 2001 Nobel Prize in Economics.

**BERLIN WALL**

On the night of August 13, 1961, police officers strung barbed wire along the border of East Berlin to keep East German citizens from fleeing to West Germany. During the previous half year about 160,000 refugees had escaped from the German Democratic Republic (GDR), bringing the total to over three million who had sought a better life and more freedom in West Germany. Because the Soviet leader Nikita Khrushchev had failed to neutralize the western sectors of the former capital of Germany in the Berlin crisis of 1958, he allowed the East German leader, Walter Ulbricht, to seal the border under the guise of protection against capitalist subversion to stop the outflow.

The barrier gradually was turned into an insurmountable concrete wall that averaged 12 feet high and 96 miles long, dividing neighborhoods, streets, and even houses. An elaborate system of fortifications with a back wall, a minefield, a jeep road, guard dogs, watchtowers, and searchlights made the wall impenetrable, and those who wanted to get out had to build tunnels, break through with trucks, fly across in balloons, or forge passports. More than 125 people died in the attempt because the border guards had orders to shoot all escapees. Because the GDR had built the wall on its side, angry Western governments could only insist on their right to cross at Checkpoint Charlie and reassure the residents of their sectors that they would not abandon them. In 1963 President John F. Kennedy expressed his solidarity with the words “I am a Berliner.”

The political effect of the wall was ambivalent. In the short run it increased cold war tensions, culminating in the Cuban missile crisis. In the medium term it stabilized the Communist regime by closing off the “exit” option and forcing East Germans to come to terms with the dictatorship of the SED (Socialist Unity Party). The wall also compelled West German leaders to accept the existence of a second German state and sign agreements with it to permit some travel through a handful of crossing points such as Friedrichstrasse. In the long run, however, the ugly edifice demonstrated symbolically that the GDR was forced to imprison its people because it remained rather unpopular. Anti-Communist leaders never tired of demanding, like President Reagan in 1987, “Mister Gorbachev, tear down this wall.”

The inhumanity of the wall eventually prompted its fall. Many East Germans continued to try to leave, supported by a West German policy that recognized them as citizens and paid ransom for their release. When the Hungarian government opened its Austrian border in the summer of 1989, tens of thousands fled, sparking mass demonstrations among those left behind in the GDR. Because that democratic awakening overthrew Erich Honecker, his successor, Egon Krenz, attempted to initiate a more liberal travel policy. Its premature announcement on November 9 inspired citizens to mass at the crossing points and force them to open, thus toppling the wall. Not only East and West Berliners but many people around the world celebrated its fall, which signified the collapse of communism and allowed Germans to reunify and Europeans to reunite.

BETTELHEIM, BRUNO 1903–1990

The lifework of Austrian-born American psychologist Bruno Bettelheim was devoted to what he called “helping others in their becoming”—improving the treatment of severely disturbed children (1950, 1955, 1967, 1974) and the parenting of all children (1962, 1976, 1987, 1993) through careful attention to their inner experience and developmental needs. His greatest achievement was his pioneering work in milieu therapy, developed when he served as director (1944–1973) of the University of Chicago’s residential Orthogenic School, whose philosophy and functioning he first described in Love Is Not Enough (1950).

Bettelheim’s thinking was strongly influenced by his experience as a concentration camp prisoner in Germany during the late 1930s (see The Informed Heart 1960). He coined the term extreme situation to describe the self-disintegrating trauma of the camp experience, where prisoners knew they might be killed any moment at the whim of the guards, but they were unable to take meaningful action because there was no predictable relationship between the prisoners’ behavior and how the guards treated them. Experiencing his own personality disintegrating under these dehumanizing conditions, Bettelheim understood that the Nazis were trying to destroy individuality—in the camps and in Germany generally—and he began to realize the centrality of autonomy in mental health. If an environment designed to promote terror, unpredictability, helplessness, and hopelessness could destroy personality, he reasoned that a therapeutic environment designed to promote safety, predictability, autonomy, and hope (“love is not enough”) could heal personality. This became the model for the Orthogenic School.

Recognizing that the “symptoms” prisoners developed—often resembling those of schizophrenia and autism—were actually survival mechanisms, Bettelheim developed an overall adaptational viewpoint that stresses active mastery and that views symptoms as adaptations to complex internal and external conditions rather than pathological dysfunctions. In The Empty Fortress (1967), his groundbreaking study of autism, Bettelheim outlined a formal developmental theory that regards autonomy as one of the two core needs of the self (along with intimacy), adumbrating an original “self-psychology” significantly different from that of Heinz Kohut (1913–1981) (Frattaroli 1994).

Bettelheim’s important contribution to the phenomenology and treatment of autism has unfortunately been overshadowed by the controversy over his theory of etiology. He viewed autism as the child’s adaptive response to the mortal terror and powerlessness of growing up in an extreme situation created by inadequate or pathological mothering. He emphasized, however, that “it is not the maternal attitude that produces autism, but the child’s spontaneous reaction to it” (Bettelheim 1967, p. 69). He thought that autistic children might have a neurologically based hypersensitivity to sensory and emotional stimuli, such that they experience ordinary negative emotions (including their own anger) as overwhelming and life-threatening. They then “try, in defense, to blot out what is too destructive an experience for them” (Bettelheim 1967, p. 398) by withdrawing into the self-protective “empty fortress” of autism.

Contrary to modern theories that autistics are neurologically impaired in their ability to recognize emotional cues, their hypersensitivity to emotions is now well documented. As Karen Zelan (2003, 2006) describes, this is much more hopeful for treatment. A collaborator with Bettelheim in his study of autism, Zelan has built on his work and begun to realize the centrality of autonomy in mental health. If an environment designed to promote terror, unpredictability, helplessness, and hopelessness could destroy personality, she rejects his ideas about bad parenting. Autistic children feel overwhelmed by—and need to withdraw from—any sensory and emotional stimulation, whether from the outside world or from within. Their development is stalled when they cannot tolerate the overstimulating presence of the very people they love—their parents. Parents may develop negative attitudes in reaction to the autistic withdrawal, but once they understand the underlying problem of hypersensitivity, Zelan finds that most parents are quite sensitive to their children’s needs and become crucially important partners in the treatment.

Shortly after Bettelheim’s death, several former students alleged that he was a sadistic tyrant who had beaten them abusively (Sutton 1996, prologue). They were students during Bettelheim’s last years at the Orthogenic School, when he was preoccupied with medical problems that forced his retirement and was worried about the school’s survival. As Sutton suggests, they may have felt cheated by his withdrawal and emotional disengagement during those years. Perhaps they felt betrayed when he killed himself after a life of preaching hope. And perhaps in the heat of these understandable emotions, they reacted, in a one-sidedly negative way, to real experiences with Bettelheim, who could be autocratic, impatient, and intimidating, and who did hit the children.

Ironically, Bettelheim’s therapeutic rationale for hitting children was to make himself a frightening but man-
The perspective expressed in this article reflects the professional and personal experience of the writer, who was inspired to become a psychiatrist and psychoanalyst through working with Bettelheim during Bettelheim’s last years at the Orthogenic School (1970–1973). He experienced the school under Bettelheim’s direction as a loving, magical, transformative place, very much the “home for the heart” described in Bettelheim’s 1974 book (Frattaroli, 1994). He has also written about Bettelheim’s contributions to psychoanalytic theory, as well as his clinical teaching and therapeutic philosophy (Frattaroli, 1992; 2001, chaps. 5, 6).

The writer saw Bettelheim hit children many times, but never maliciously or abusively. He hit them when their behavior was unsafe or threatened the staff’s ability to manage groups. Bettelheim’s practice of hitting was deliberate, controlled, predictable, and safe.

As former student Stephen Eliot (2003, chap. 7) describes, the children knew exactly what to expect from Bettelheim, an open-handed slap on the face that was humiliating enough to be a deterrent, but not physically harmful.

Bettelheim often said that because his hitting of children was not done in anger, it was much kinder than what the children would otherwise have done to themselves—out of guilt and self-hatred—or what they may have provoked staff to do to them in anger. Bettelheim’s regular practice, immediately after hitting a child, was to talk with staff members about the situation that had required his intervention, pointing out where they had missed or misunderstood important signals that could have told them what the child needed. His keen sense of the children’s needs and vulnerabilities in these discussions confirms that he was not angry with them. One cannot be in an abusive rage at a child one minute and show a thoughtful, empathic respect for that child the next minute.

Standard methods of behavioral control used in hospitals nowadays—any of which can become abusive in the angry impulse of the moment—include leather restraints, locked and padded seclusion rooms, and powerful psychotropic drugs, often used indiscriminately, always without regard for their long-term impact on growth and development (about which nothing is known). Having experienced all these methods in action as a psychiatrist, this writer considers Bettelheim’s approach to have been more humane and less destructive to patients’ trust and self-esteem. The writer does not advocate such a treatment approach for anyone else, but it was appropriate for Bettelheim and the unique conditions of the Orthogenic School, which functioned more like an extended family than a hospital.

The above account is entirely this writer’s, but it is consistent with Sutton’s (1996, chap. 14) more detailed and well-documented discussion of Bettelheim’s practice of hitting. At stake in this controversy is arguably the most important twentieth-century contribution to the wise, humane, ethical, and effective treatment of severely disturbed patients.

BEVERIDGE CURVE

The term Beveridge curve describes the negative relationship between the unemployment rate and the vacancy rate in an economy’s equilibrium. It is named after William Henry Beveridge (1879–1963), a British economist and reformer and one of the preeminent inspirers of postwar British welfare state. His seminal reports to Parliament in 1942 and 1944 (Social Insurance and Allied Services and Full Employment in a Free Society) promoted a comprehensive social program aimed at reaching full employment, and they laid the foundation for the later development of an improved social security system to support people “from the cradle to the grave,” as well as the National Health Service in Britain.

Labor markets in equilibrium are characterized by the coexistence of people seeking jobs and vacant jobs employers want to fill. This is the result of frictions that make the process of matching job seekers to job vacancies costly and time consuming. This process can be approximated through a matching function that relates the number of hires (or job matches) \( M \) to the number of unemployed workers \( U \) and job vacancies \( V \).

The function is increasing in both arguments; that is, it assumes that the number of hires rises when more workers and employers search in the labor market. In equilibrium, when the number of job separations equals the number of matches, it is possible to identify a negative relationship between unemployment and job vacancies. This negative relationship is known in the literature as the Beveridge curve.

Cyclical labor market dynamics are commonly reflected by movements along the Beveridge curve. Expansions are characterized by higher vacancy rates and lower unemployment rates, whereas the opposite is true for contractions. Positive comovements of the job vacancy rate and the unemployment rate can be interpreted instead as the result of changes in the structural properties of the underlying job matching process—that is, in the capacity of the unemployed to be matched to job vacancies. These structural changes can be imputed to a number of factors, such as institutional change, mismatch between the skills of the unemployed and the skills required by new jobs, search effort, or effectiveness. According to this interpretation, a shift to the right of the Beveridge curve may be associated with an increase in equilibrium unemployment. Economic policy then should be aimed at increasing the effectiveness of job matching, shifting the Beveridge curve to the left and thus alleviating the underutilization of the available labor resources in the economy.

On the empirical side, there are a number of difficulties that complicate the estimation of a Beveridge curve. First, the researcher often lacks proper vacancy data and therefore resorts to vague approximations, using available series whose relationship with the vacancy rate may not be constant over time. Second, the pool of workers available for a match may include other categories of workers in addition to the unemployed, such as employed workers searching for new jobs, or even individuals only temporarily out of the labor force. Third, shifts in the Beveridge curve are usually hard to detect in a nonarbitrary way.

BHAGWATI, JAGDISH

1934–

Jagdish Bhagwati was born and raised in India. He went to Cambridge University in 1954 and graduated from there in 1956 with a first in Economics Tripos (Tripos...
refers to the system of honors degrees and examinations at Cambridge). He then studied at the Massachusetts Institute of Technology (MIT) and Oxford, returning to India in 1961 as professor of economics at the Indian Statistical Institute in New Delhi. In 1963, he moved to the Delhi School of Economics as professor of international trade. He visited Columbia University during 1966–1967 and joined the permanent faculty of MIT in 1968, where he later became the Ford International Professor of Economics. In 1980, Bhagwati joined Columbia as Arthur Lehman Professor of Economics and Professor of Political Science. In 2001, he became a University Professor at Columbia University.

Bhagwati has served as economic policy adviser to the director-general of the General Agreement on Tariffs and Trade (GATT) (1991–1993), as special adviser to the United Nations (UN) on Globalization (2001), and as an external adviser to the World Trade Organization (WTO). He also recently served as a member of UN secretary-general Kofi Annan’s advisory group on New Partnership in Africa’s Development (NEPAD) and was a member of the Eminent Persons Group on the future of the UN Conference on Trade and Development (UNCTAD).

Bhagwati has published more than 300 articles and fifty volumes. He is regarded as one of the foremost international trade theorists of his generation. His very first article, “Immiserizing Growth: A Geometrical Note,” published in the Review of Economic Studies in 1958, is regarded a classic and spawned a large body of literature. In it, he showed that growth that expanded a country’s export sector could so drastically worsen its terms of trade as to actually lower its real income and welfare.

Bhagwati’s most influential scientific contribution is “Domestic Distortions, Tariffs, and the Theory of Optimum Subsidy” (1963), written jointly with V. K. Ramaswami. This paper was written at a time when the relevant analytic literature was characterized by ambivalence with respect to the superiority of trade over autarky. It had been pointed out that when domestic distortions such as unionized wage or externalities existed, there was no guarantee that free trade would be superior to autarky. Bhagwati and Ramaswami demonstrated that once an appropriate policy was adopted to eliminate the existing distortion, the case for free trade was restored. They also introduced the idea of policy ranking. In the context of the wage-distortion model, they showed that from a welfare perspective, wage subsidy was the first best instrument, followed by output subsidy and tariff in that order.

Subsequently, Bhagwati led the way in numerous areas of research, including brain drain, illegal international trade, noneconomic objectives and optimal policy interventions, directly unproductive profit-seeking (DUP) activities, nonequivalence of tariffs and quotas, and preferential versus multilateral trade liberalization. He coauthored many of the contributions in these and other areas with T. N. Srinivasan of Yale University. The two together also wrote the influential book Foreign Trade Regimes and Economic Development: India.

Currently, Bhagwati is the foremost advocate of free trade. His critics have sometimes argued that he only cares about free trade and does not pay social issues such as labor and environmental standards, income equality, and the gender gap the importance they deserve. Yet such criticisms are the result of a superficial reading of his writings. In his recent celebrated book In Defense of Globalization (2004), he carefully dissects all of the important and controversial social issues and advocates their promotion rather than playing them down in favor of free trade. Where he differs from his critics is in the use of trade protection or trade sanctions as instruments for achieving these objectives. Instead, he advocates the use of multiple instruments to achieve multiple objectives. Thus, for example, he recommends using the instrumentality of the International Labour Organization and nongovernmental organizations to promote labor standards and the World Trade Organization to promote trade liberalization.

BICAMERALISM
Parliaments are unicameral or bicameral. In a unicameral parliament all members of parliament sit in the same chamber and vote on major policy decisions. In a bicameral parliament members meet and vote in two separate chambers, usually called the lower house and upper house. The lower house is usually based proportionally on population with each member representing the same number of citizens in each district or region. The upper house varies more broadly in the ways in which members are selected, including inheritance, appointment by various bodies, and direct and indirect elections.

In most bicameral legislatures, the lower chamber predominates. Especially in parliamentary systems, in which the cabinet is responsible for the parliament, ensuring that the cabinet is responsible only to one chamber is critical. Usually, the upper house is able only to delay legislation passed by the lower house. Sometimes the upper house can veto certain types of legislation. In Germany, for instance, the Bundesrat has veto power over legislation that affects the power of the states (the Länder). In Britain the House of Commons is the dominant partner: Ministers and governments emerge from the lower chamber and remain accountable to it.

A majority of the world’s parliaments are unicameral. However, in 2000, 37 percent of the world’s 178 parliaments had two chambers. This proportion has decreased since World War II as several established democracies have abolished their second chamber, and as new, unitary, and postcommunist states have adopted unicameral assembly. On all continents unicameral assemblies are more common than bicameral ones. For the most part bicameral systems may be found in South and North America and Europe. On the contrary, in Africa and Asia bicameral systems are rather unusual.

According to the political scientist Andrew Heywood (1997), the major benefits of bicameralism are:

- Second chambers check the power of first chambers and prevent abuses of majoritarian rule.
- Bicameral assemblies more effectively check the power of the executive, because there are two chambers to expose the failings of government.
- Two-chamber assemblies widen the basis of representation, allowing each house to articulate a different range of interests and respond to different groups of voters.

- Second chambers act as a constitutional safeguard, delaying the passage of controversial legislation and allowing time for discussion and public debate.

The major drawbacks are:

- Unicameral assemblies are more efficient, because the existence of a second chamber can make the legislative process unnecessarily complex and difficult.
- Second chambers often act as a check on democratic rule, particularly when their members are nonelected or indirectly elected.
- Bicameral assemblies are a recipe for institutional conflict in the legislature, as well as government gridlock.
- Second chambers introduce a conservative political bias by upholding existing constitutional arrangements and, sometimes, the interests of social elites.

In terms of authority and political power bicameral legislatures show large variation. The weakest upper chambers are hardly more than retirement posts for politicians of great merit. On the other hand, with respect to political influence the strongest upper chambers are comparable with the lower chamber or the executive power.

BIGOTRY

Throughout human history, civilizations have been plagued by the problems that result from people's prejudice and bigotry toward one another. In this context, prejudice is a negative attitude that occurs when people prejudge disliked others, and bigotry is an extreme form of it. Social scientists have written extensively about the correlates of prejudice because of its relationship to group conflict and violence (e.g., Janowitz 1969). Much of this attention has focused on the connections between group conflict and a host of social phenomena that are associated with prejudice, including though not limited to stereotyping, rioting, terrorism, and, not the least among them, bigotry (e.g., Hovland and Sears 1940; Green et al. 1998). Common terms related to bigotry include ethnocentrism and intergroup hatred.

Bigotry refers to extreme intolerance of members of a socially recognized and vilified out-group. An out-group is a group other than the one in which individuals perceive themselves to belong. Prejudice refers to negative attitudes toward members of a group that may or may not be expressed. Though similar (e.g., they both refer to a bias in perception of others), the two terms—bigotry and prejudice—may be distinguished, with bigotry representing a more extreme and brazen form of prejudice.

Bigotry, though not an intractable problem, is one that has shaped the nature of interaction between groups of people throughout history and around the world. For example, intergroup relations between blacks and whites in the United States, Germans and Jews in twentieth-century Europe, Israelis and Palestinians in the Middle East, Africans and Afrikaners in South Africa, heterosexual and gay people, and men and women have all been affected by bigotry and bigoted attitudes. Bigotry and the corresponding problems that ensue from it remain high on the list of "social evils," and most people perceive the bigot to be a person who is obstinately narrow-minded, antisocial, and lacking the moral acuity that many believe themselves to possess.

In general, researchers who study bigotry recognize the difficulties involved in identifying its causes. This is because there are often important related variables to consider, including differences (or similarities) in cultural orientation, national identity, and religious background, as well as contact and familiarity—all of which can be associated with bigotry. Not surprisingly, more is known about the consequences of bigotry (e.g., harassment, assault, riots, terrorism) than about the factors that give rise to it.

Researchers have employed a host of methods to assess the presence of bigotry. In earlier years, attempts to measure bigotry often involved direct questionnaires in which respondents indicated the degree to which they liked or disliked an out-group. More recently, changing social norms prohibit direct expression of prejudice and bigotry in most settings. Consequently, researchers have employed more covert measures, such as reaction-time tests in which the time needed to respond to a stimulus is taken as an indirect indicator of a person's attitude. In other cases, behavioral measures, such as seating choice and proximity to a member of an out-group, have been used as indicators of bigotry.

STUDIES OF BIGOTRY

Importantly, some of the earliest social science research addressing the problem of bigotry focused on patterns of interaction and violence perpetrated by whites against African Americans in the United States. Until the late 1950s, blatant racism and physical violence directed at African Americans was normative and well entrenched within the social fabric of American society. Whereas some blamed white fears about miscegenation (i.e., interracial sexual relations) for the collective violence directed at the newly freed class of citizens, others generally attributed the problem to the expanding rights of African Americans.

Contemporary research and theory on bigotry can be conceptualized along a continuum. At one end are those theories that locate the causes of bigotry outside of the individual at the societal level (i.e., the macro level of analysis). These types of theories are largely context dependent. At the other end of this conceptual continuum are explanations for bigotry that attribute causality to internal factors such as deficiencies in the individual's personality, limitations in information-processing capacities, or physiological and biological mechanisms.

Many of the efforts toward understanding the problem of bigotry have involved individualistic accounts of prejudice focusing on such cognitive processes as stereotyping, categorization, and learning. In the U.S. tradition of social psychology, researchers have tended to focus on the individual's thought processes and experiences while overlooking or minimizing ways that the wider social context can instigate bigotry (Bar-Tal and Teichman 2005). In contrast, researchers outside of the United States, as well as many of those within the discipline of sociology (e.g., Feagin and Feagin 1986), have focused upon the institutional and structural factors that can be both causes and effects of bigotry. According to this approach, current institutional policies and organizational structures continue to discriminate because they were established in the past by those most privileged by discriminatory policies. Because of these policies, people who were targets of prejudice in the past continue to experience discrimination long after explicit expressions of bigotry and acknowledgment of prejudice have ceased to occur.
Although interest in studying bigotry has varied over the years, a renewed interest in the topic is evident among researchers addressing issues related to cyberhate, terrorism, and religious and nationalistic fanaticism. In the case of cyberhate, the speed of the Internet and its widespread accessibility make the spread of bigotry almost instantaneous and increasingly available to vulnerable populations (Craig-Henderson 2006). As for the relationship between bigotry and nationalism, there are a host of researchers studying the Arab-Israeli conflict in the Middle East (e.g., Bar-Tal and Teichman 2005). That particular conflict has roots in the Zionist occupation of the country of Israel, formerly known as Palestine. Because of the historical realities that have created the state of Israel, today’s Arabs and Jews in that region have very distinct group identities that have given rise to their intergroup conflict. Social science researchers who study this kind of group conflict have demonstrated that the strength of identification with one’s in-group is associated with one’s expressed bigotry toward the out-group. In many situations, the more strongly one identifies with an in-group, the more bigoted one is against members of the out-group.

Bigotry can be minimal and manifested in avoidance or social exclusion of the out-group, or it can be severe and deadly. In 1998 James Byrd Jr., an African American man in Jasper, Texas, was murdered by white supremacists who dragged him to death behind their pickup truck after offering him a ride home. As members of a white supremacist group, Byrd’s murderers were extreme in their bigotry. As a black man, Byrd was perceived by his murderers to be a member of a despised out-group.

Similarly brutal attacks have targeted sexual minorities. In 1998 the murder of the college student Matthew Shepard near Laramie, Wyoming, was attributed to anti-gay bigotry. Most public opinion polls reveal continuing evidence of this form of bigotry (Herek 2000). Shepard’s bigoted murderers were highly prejudiced toward gay people. Other examples of well-known bigots include David Duke, the former leader of the Ku Klux Klan; Nazi chancellor of Germany Adolph Hitler (1889–1945); and French politician Jean-Marie Le Pen.

RESOLVING BIGOTRY

One popular and long-standing idea within the social psychological literature has been that bigotry can be reduced with intergroup contact. That is, through contact with one another under ideal conditions, formerly bigoted outgroups could come to look favorably upon one another and thereby attenuate conflict and bigotry. However, this optimistic outlook has fallen out of favor in recent years as its theoretical underpinnings have been challenged by a number of researchers studying bigotry. For example, when one considers the pervasiveness of gender bias against women and the paradoxical intimacy that characterizes relations between heterosexual males and females, it becomes clear that contact, while necessary, is not sufficient to eliminate bigotry. Furthermore, there is relatively little research investigating the extent to which contact between different real-world racial and ethnic groups can actually breed harmony. How then to solve the problem of bigotry? The best strategy is one that includes education, interaction, and legislation. Indeed, any efforts aimed at eliminating bigotry must involve attention to each aspect of this tripartite approach.

security matters between two states. Bilateralism has both costs and benefits, and there is a debate on its merits relative to unilateral or multilateral approaches.

States have traditionally related to each other on a bilateral basis. They recognize each other as states and agree to send ambassadors to each other’s capital. Diplomatic relations can be unilateral, of course, but unless relations are bilateral, some tensions are likely. China and the United States concluded a Joint Communiqué on the Establishment of Diplomatic Relations on January 1, 1979, and formally established embassies in Beijing and Washington, DC, on March 1, 1979. The result was a normalization of relations, which had often been turbulent between 1949 and 1972.

Economic bilateralism is common. In trade, for example, countries have struck bilateral agreements in which they mutually agree to lower their tariffs. The effect is to encourage trade between the two sides to their mutual benefit. Such arrangements can also lead, however, to conflict with third parties excluded from such benefits. Bilateral agreements tend to be more common during or just after periods when economic nationalism (unilateralism) dominates or when multilateral options are stalled.

In security affairs, bilateralism is also found in agreements between states to come to each other’s defense if attacked or threatened by a third party. Otto von Bismarck negotiated such a treaty with the Austrian Habsburg Empire in 1879. That treaty also antagonized Russia and helped fuel insecurities that gave rise to World War I. During the cold war, the United States and the Soviet Union concluded a number of agreements to mutually limit nuclear weapons, such as the Strategic Arms Limitation Treaty (SALT) and the Strategic Arms Reduction Treaty (START).

Bilateralism has advantages and disadvantages in comparison with the alternatives. With respect to unilateralism, it offers less freedom of action. Yet it also offers the ability to realize mutual gains that may be available only from acting jointly, for example, greater economic activity from freer trade, reduced armament burdens from agreed limitations, and greater security from cooperation against external threats.

With respect to multilateralism the calculus reverses itself. Bilateralism affords greater freedom and efficiency of action because fewer actors are involved. The League of Nations and its successor, the United Nations, have often been criticized for ineffectiveness because too many parties are involved.

Yet bilateralism is too costly and is insufficient to deal with some world problems. For example, the multilateral World Trade Organization is a much easier way to organize free trade than to have every country negotiate bilateral free-trade agreements with each other. And bilateral agreements would be unwieldy and not comprehensive enough for a systemic problem like global warming. The efficacy of bilateralism depends on the issue and the situation.

BILL OF RIGHTS, U.S.

The first ten amendments to the U.S. Constitution are known as the Bill of Rights. The guarantees of the Bill of Rights include freedom of religion, the rights of expression and association, the right to privacy, the right to due process, and freedom from unjust restraint or trial and from cruel and unusual punishment. The U.S. Bill of Rights has served as a model for other nations in the development of their own constitutions.

The U.S. Constitution was shaped in large part by compromises between Federalists who advocated a strong, centralized government, and Anti-Federalists who believed that the balance of power should favor the states. One of these compromises involved the adoption of a bill of rights—an enumeration of the fundamental and inalienable rights of citizens.

A proposal to include a bill of rights was rejected by the Constitutional Convention of 1787. The Federalists believed that a bill of rights was unnecessary since the government possessed only those powers enumerated in the Constitution. They asserted that state constitutions protected individual rights and that the federal Constitution did not repeal those protections. The Federalists also feared that a listing of specific rights would endanger rights that were not listed. Not persuaded by these arguments, some Anti-Federalists withheld their signatures from the final document because of the absence of a bill of rights. Others proposed that a second constitutional convention be held to draft a bill of rights.

At state conventions to consider ratification of the Constitution, opposition focused on the failure to include a bill of rights. Anti-Federalists asserted that the

INTERNATIONAL ENCYCLOPEDIA OF THE SOCIAL SCIENCES, 2ND EDITION
Constitution lacked sufficient safeguards for individuals against abuses of power by the federal government, and they pushed to postpone ratification until the Constitution was amended appropriately. The Federalists stood their ground initially, but when it became apparent that ratification was in jeopardy, they agreed to a compromise—they would accept proposed amendments for inclusion in a bill of rights with the ratification instruments of the states.

James Madison (1751–1836), who was elected to represent Virginia in the First Congress, had made a campaign pledge to his Anti-Federalist constituents that he would sponsor a bill of rights and work toward its passage. In June 1789 Madison introduced a proposed bill of rights in the U.S. House of Representatives. Madison’s bill of rights reflected the recommendations of the state ratifying conventions, but it also drew upon the Magna Carta of 1215, the English Bill of Rights of 1689, and the Virginia Declaration of Rights of 1776. Congress approved twelve of Madison’s proposed amendments, and ten were ratified by the states. The Bill of Rights was added to the Constitution in 1791.

The Bill of Rights limits the powers of the federal government, but in the late nineteenth century the U.S. Supreme Court began using the Fourteenth Amendment to make the Bill of Rights applicable to state governments as well. According to the Court’s incorporation doctrine, the Fourteenth Amendment prohibits states from violating those provisions of the Bill of Rights that represent the “fundamental principles of liberty and justice which lie at the base of all our civil and political institutions” (Hebert v. Louisiana 1926). Between 1897 and 1969, the Supreme Court made nearly all of the protections of the Bill of Rights binding upon the states.

BIN LADEN, OSAMA
1957–

Osama bin Laden was born the seventeenth of Muhammed bin Laden’s fifty-two children and the seventeenth of his twenty-four sons, in Riyadh, the capital of Saudi Arabia, on March 10, 1957. Osama bin Laden was, however, the only child of Alia Ghanem of Syria, perhaps the most beautiful of Muhammed bin Laden’s many wives, but different and separate from the Saudi clan and soon to be divorced by her husband. Muhammed bin Laden began life as a poor Yemeni bricklayer, uneducated and one-eyed. He became an enormously wealthy building contractor in Saudi Arabia after crafting intimate ties with the royal family.

Osama bin Laden’s youth was spent in Hejaz, a southern Arabian province. In 1976 he graduated from private school, the Al Thagher Model School, near the port town of Jedda where he grew up. Described by former teachers and classmates as an outstanding student, bin Laden spent his extra time involved in a for-credit after school Islamic study group for exceptional students. Many believe it could be there that he first acquired a formal education in jihad. Classes were on the principles of the Muslim Brotherhood, an Islamist organization founded in Egypt in the 1920s and based on Islamic activism, political consciousness, and jihad. Bin Laden graduated from Jedda’s prestigious King Abel Aziz University with a degree in civil engineering. The stories of bin Laden as a hard-drinking partygoer in Beirut in his youth are almost certainly wrong (and probably confuse him with one of his many brothers or other family members). On the contrary, at the university bin Laden was earnest and studious. He took the Qu’ran, at least his fundamentalist reading of it, to heart.

In 1979 the Soviet Union invaded Afghanistan in what would turn out to be a disastrous war that would lead to Soviet defeat and the collapse of the empire. There immediately arose throughout the Muslim world a mythic call for jihad—embraced by the Saudi royal family itself—in defense of the Islamic peoples of Afghanistan against the godless “infidel” Russians. Osama bin Laden responded warmly to that call. At first he raised money for the cause, then in the early 1980s, with his spiritual mentor, Abdullah Azzam (1941–1989), established the Maktab al-Khidamat (services offices) in Pakistan’s University of Peshawar to direct support and resources to the fighters out in the field. In 1986 the twenty-nine-year-old Osama bin Laden added a heroic battlefield experience to his expanding mythic vita at the battle of Jaji. In his account, which is probably as much inspirational fairytale as actual history, he and the Afghan fighters were thirty meters from the Russians. He came close to being captured, but was so peaceful in his heart that he went to sleep for a while. Mortars fell around him and miraculously failed to explode. “We beat the Soviet Union,” he said (bin Laden, 2005). “The Russians fled.”

Bin Laden’s Islamist triumphalism and his insistence on the continuation of jihad made him a nuisance in
Saudi Arabia, which forced him to leave the country in 1991 and finally revoked his citizenship in 1994, despite his impeccable family ties. He spent the next half-decade in Sudan, a remote and lawless land in which he could operate mostly outside of international control as he plotted his next move. One important event in these years that led to his further radicalization was the Gulf War of 1991. He was appalled that Saudi Arabia would allow American troops to be based on what he saw as sacred Saudi soil as they massed troops for an attack against a fellow Muslim country. He personally despised Iraqi president Saddam Hussein (1937–2006) but regarded Iraqis as brethren in faith. Bin Laden became so extreme in his extravagant rhetoric against the royal family that the Saudi government in 1994 finally revoked his citizenship and tried to strip him of all of his assets, though by then his considerable fortune was invested in many global enterprises and out of their reach.

But Sudan in turn eventually succumbed to pressure from the United States, and in 1996 bin Laden was expelled. A man without a country, he chose to relocate in what was by then an Afghanistan controlled by the fundamentalist Taliban. It was there that bin Laden breathed new life into Al-Qaeda, or base, for global terrorist operations, an organization founded in 1988 as the Soviets were pulling out of Afghanistan. For the next five years he operated with virtual impunity in a remote land under Islamist control. In the Afghan camps, thousands of jihadis received training in terrorism. They were committed to the ideals of global jihad and to Osama bin Laden, to whom they took a personal vow of loyalty. Most of those in the camps were foot soldiers, but some, such as Khalid Sheikh Mohammed (who devised what was called the “planes projects” or what became the terrorist attacks of September 11, 2001) and Mohammed Atta (the head of operations for the 9/11 attacks) were central figures in the Afghan camps.

Bin Laden’s chief lieutenant was Ayman al-Zawahiri, an Egyptian medical doctor who had been tortured in Cairo prisons. Al-Zawahiri had been inspired in the 1950s and 1960s by the writings of Sayyid Qutb (1906–1966), an Islamist intellectual who was hanged in prison by Egyptian president Gamal Abdel Nasser (1918–1970). It was Qutb who resurrected an idea at least seven centuries old that violent jihad was at the center of the faith, that purification of Islam went along with eradication of infidels, and that the only goal worth pursuing was the re-creation of a world modeled on that which the Prophet specifically created. Bin Laden, of course, knew the writings of Qutb, though probably mostly through others inspired by Qutb, such as al-Zawahiri and Azzam. Al-Zawahiri, however, was important in other ways to bin Laden. Al-Zawahiri was not an effective leader himself, and in 1996 he merged his Al-Jihad into bin Laden’s Al-Qaeda, formally joining the long Egyptian tradition of the Muslim Brotherhood with Wahhabi fundamentalism. Al-Zawahiri proved a formidable ally, able to conceptualize a global jihad and help implement it organizationally.

Al-Qaeda was structured along the lines of a multinational corporation. Bin Laden was the CEO, and each unit, which could thrive apart from the other divisions, was headed by the equivalent of a vice president. It was a structure intended to survive attack and disruption. Funding came in part from bin Laden himself, though his personal fortune was far less than most imagined and probably not more than a million or so dollars a year. Most funding came from donations and a global network of “charities.” Until 9/11 bin Laden did not seem short of funds.

It was his ideology of jihad that made bin Laden remarkable in these years. He was a religious fanatic and a well-organized businessman, a mystic and master of bureaucratic detail, a man plotting mass destruction and death, and a soft-spoken dreamer who reinvigorated an Islamist movement in ways that have not been seen in the Muslim world since Saladin in the twelfth century. On August 23, 1996, in his “Declaration of Jihad” bin Laden called on all his “Muslim brothers” to help him share in the jihad against the “enemies of God, your enemies the Israelis and Americans” (bin Laden 2005, pp. 23–30). And on February 23, 1998, in his declaration of the World Islamic Front, bin Laden declared a kind of universal declaration of war against “Jews and Crusaders” and declared it was an “individual duty incumbent on every Muslim in all countries” to kill Americans and their allies (bin Laden 2005, pp. 58–62). This declaration of war took the fight outside of the sectarian battles in the Middle East and into the very heart of the enemy lands. Bin Laden wanted concrete political things: American troops out of Saudi Arabia, the defeat of Israel and the liberation of the Palestinians, and the overthrow of corrupt secular Muslim rule in the Middle East. But he also harbored millennial dreams involving the annihilation of American, Western, and Jewish culture in a forge of violence that was redemptive and purifying.

On September 11, 2001, Al-Qaeda struck New York City and the Pentagon near Washington, D.C., in an extraordinarily successful terrorist attack. That the attacks worked as well as they did was also in large part due to pure luck on bin Laden’s part. The World Trade Center collapsed in an inferno of fire mainly due to failures in the architectural conception of the buildings themselves. The whole operation cost well under half a million dollars, and it has caused several hundred billion dollars in direct and indirect damage.

But the spiritual and political costs of 9/11 are incalculable. The 2,749 people who died that day in New York...
 lingered in the air, literally, and many were inhaled by New Yorkers with dust from the collapsed towers. It all made for incomplete mourning that certainly lasted through the months of clearing away the debris but also into the two wars that soon followed, the second of which is the extended war in Iraq. Many live with a special dread from that day, and it serves to symbolize the malevolence of contemporary history. Most Americans believe, if asked in the right way, that if Osama bin Laden had possessed nuclear weapons before 9/11 he would have placed one on a plane crashing into those towers.

Thankfully, Osama bin Laden did not possess such a weapon. As of 2007, he was hiding somewhere, probably in the mountainous border region of Pakistan and Afghanistan, basically out of commission, though by remaining alive he inspires others to act in his name and may even continue to direct some actual operations. Bin Laden’s legacy is mixed. There is no question he has changed the world and the violence he directed may occasion a realignment of power in the relationship between the West and the Muslim Middle East. It also energized the new terrorism for many years and disrupted advanced economies in ways few could have imagined possible before 9/11. On the other hand, the violence of bin Laden and Al-Qaeda may backfire for the Muslim world, leading to disruption and civil war and further isolation, rather than renewal along the lines of Islamist fantasies. It may be many years before we will know with any degree of certainty whether the twenty-first century will be relatively free of terrorism and violence.

BIOETHICS

The field of bioethics, as distinct from medical ethics, has existed since the 1960s. Unlike medical ethics, which for centuries has examined the duties and responsibilities of physicians to their patients and to other doctors, the development of bioethics can be traced to the rapid progress in technology and science experienced in the United States in the 1960s. Organ transplantation, chemotherapy, kidney dialysis, respirators, the contraceptive pill, genetic screening, and intensive care units were extraordinary medical breakthroughs that were seen as highly beneficial but also costly and sometimes harmful. This explosion of technological success brought in its wake a set of daunting ethical dilemmas that medicine, academics, legislators, and the public had never previously been forced to face.

In the wake of these developments, issues of health-care access and rationing, withdrawal and withholding of lifesaving care, dignity in dying, and how to define death and manage the high cost of medical care now loomed large as urgent ethical quandaries. At the same time, societal changes placed greater emphasis on individual autonomy and rights, which prompted the public to press the
field of medicine for more patient involvement and control over medical treatment. The ethical dilemmas generated by these advances in science and medicine required interdisciplinary study and reflection that traditional academic disciplines were ill-equipped to handle. In response to these pressing ethical problems, scholars began to venture outside of their traditional subject matter to discuss, debate, and write about these new dilemmas, and bioethics became a new area of academic attention.

Some of the original dilemmas are still at the core of bioethics today. The field now focuses ethical problems in clinical, preventive, and research medicine that involve truth telling, informed consent, confidentiality, end-of-life care, conflicts of interest, nonabandonment, euthanasia, and substituted judgment for incompetent persons. Bioethics has established both the right to informed consent and the right to control one’s medical treatment as key tenets of American law and ethics. With each new technological breakthrough, the field of bioethics expands its scope to address new ethical dilemmas, most recently those involving the human genome project, stem cell research, artificial reproductive technologies, the genetic engineering of plants and animals, the prospect of human reproductive cloning, preimplantation genetic diagnosis of embryos, nanotechnology, and xeno-transplantation. Bioethics has also more recently begun to reflect on the health-care challenges faced in developing nations, such as whether national or local standards should govern the conduct of medical research or the problems of rationing access to innovative treatments in nations besieged by devastating epidemics such as malaria or AIDS.

Since the 1960s, the field of bioethics has gained legitimacy as an independent academic discipline, and that new status has brought significant changes in the structure and institutions of the field. Originally, the institutions of bioethics were independent think tanks. Today, the trend is the creation of academic bioethics departments, either within a medical school or school of arts and sciences. The professionalization of bioethics has taken it from the academic margins to an accepted place within universities, hospitals, regulatory bodies, the media, and industry.

BIOTERRORISM

Terrorism is the intentional use or threat to use violence against civilians or civilian targets in order to attain political ends. Bioterrorism uses microorganisms or toxins that are derived from living organisms to produce death or disease in humans, animals, or plants. Animals and plants are of concern because of the economic consequences of terrorism on food production and exports.

Historically, terrorists have relied primarily on conventional weapons such as guns and explosives to further their objectives. While conventional weapons will continue to be the most accessible, biological weapons are becoming increasingly available, and terrorists have turned from low-casualty, high-visibility targets to targets that can result in mass casualties, where biological weapons are an ideal choice. One of the most important advantages of biological weapons is cost. One dollar’s worth of anthrax can kill as many people as $2,000 worth of conventional explosives.

Biological agents had been used as weapons only twice in the United States. On September 9, 1984, a religious cult, the Rajneeshees, sprayed Salmonella typhimurium on salad bars in The Dales, Oregon, causing 751 cases of food poisoning. No deaths occurred. The second U.S. attack occurred in September 2001, when Bacillus anthracis spores were distributed through the U.S. Postal Service. This attack resulted in twenty-two cases of anthrax infection and five deaths. The production of this...
Weapons-grade anthrax required a high degree of scientific knowledge and sophisticated equipment. Approximately two grams of the anthrax spores, if aerosolized effectively, could kill tens of thousands of people. Although the 1995 subway attack in Tokyo by the religious extremist group Aum Shinrikyo used a chemical agent, Aum had previously attempted to use anthrax and botulinum toxin.

Terrorists have access to hundreds of potential biological agents to use as weapons. These weapons can be in liquid or powder form, and they can be dispersed successfully as an aerosol if particle sizes are small enough to enter the lungs. The particles can be aerosolized from a stationary location or from a moving source either outdoors or indoors. Furthermore, many biological agents can be delivered in food or water.

The North Atlantic Treaty Organization (NATO) has identified thirty-one potential agents that terrorists can use. The United States Army Medical Research Institute of Infectious Diseases (USAMRIID), has reduced this list to six primary agents: anthrax, smallpox, plague, tularemia, botulinum toxin, and agents of viral hemorrhagic fever. Many of these agents cause diseases that present-day physicians have never seen, decreasing the likelihood that they can be rapidly diagnosed.

The United States, United Kingdom, and other countries have developed national response plans to deal with natural disasters and acts of terrorism, including bioterrorism. These plans will be important for mounting a coordinated response to a bioterrorist attack. Equally important are plans to respond to a global outbreak of an infectious disease because similar response mechanisms will be used for bioterrorism. Both the World Health Organization and the United States released plans in 2005 for responding to a pandemic of influenza. Other countries are developing similar plans, and these plans will be important not only for a naturally occurring infectious disease but also for a bioterrorist attack.

An effective response to an attack will also require modifying existing laws so that governments can maximize their response efforts. Governors must be able to suspend provisions that regulate how state agencies do business in order for them to rapidly respond to public health emergencies. Public health authorities must be able to close and order the decontamination of buildings and destroy or safely dispose of any material or human remains that have been contaminated. They must also be able to take every available measure to prevent the transmission of infectious disease, including the use of isolation and quarantine, and to ensure that all cases of contagious disease are properly controlled and treated. Laws will also need to be modified to allow for the rapid purchase of pharmaceutical agents and the rationing of scarce supplies. Public health authorities must be able to provide temporary licenses to out-of-state health care providers and modify liability laws to protect state officials and health care providers during a declared emergency.

Although extreme measures are called for during an emergency such as a bioterrorist attack, civil liberties must be protected. Gross negligence or willful misconduct should not be exempt from liability. Provisions of the law must be in place for rescinding the emergency orders when health conditions that caused the emergency no longer pose a high probability of a large number of deaths. Lawyers have developed a model emergency health powers act that can be used to strengthen government’s ability to respond to bioterrorism and at the same time protect civil liberties.

BIRTH CONTROL

Birth control refers to the means used to limit or space human fertility. The technological development of these means, the organization of their use, and the fairness of their application are the province of scientists, policymakers, religious leaders, and the users of birth control. The definition includes recent methods such as condoms, sterilization, intrauterine devices, and the birth control pill. It also includes older methods, such as abortion, prolonged nursing of infants, periodic abstinence from sex, herbal tonics, and coitus interruptus.
The question of the comparative effectiveness of various techniques often comes up in discussions of birth control. Abortion, some forms of surgical sterilization, and complete abstinence from intercourse are the most effective at preventing births. Yet, effective birth prevention is only one of the goals considered by users of birth control and by the persons and institutions promoting its use. Safety and ease of use are, for example, other important dimensions of birth control technologies. In fact, limiting births is sometimes not even the main goal of a birth control practice, but its side effect. For example, inducing an abortion could be a means to save a woman’s life. Likewise, the contraceptive effect of prolonged nursing may be subordinate to a woman’s inclination to breast-feed. Moreover, practitioners of periodic abstinence and coitus interruptus can see these actions as enhancing their own self-worth because of the sacrifices they entail.

In 1798 the English economist Thomas Robert Malthus (1766–1834) argued for the eventual scarcity of natural resources given the rate of population growth worldwide. This argument became the basis of the first organized efforts to limit population sizes in the West. The fact that most of these efforts were directed at the poor, the ill, and the criminal made for an enduring link between birth control and eugenics, the belief that only the “fittest” humans should reproduce. Among the methods touted for their effectiveness were condoms, which became increasingly popular after 1860 with the use of rubber in their manufacture, replacing animal intestines and silk sheaths. Douching solutions and vaginal pessaries also became more effective in the nineteenth century. Sterilization required developments in medical antisepsis and anesthesia, which were only coming of age in the 1870s.

Opponents to organized birth control emerged in the 1870s; they included Anthony Comstock (1844–1915), founder of the New York Society for the Suppression of Vice, and the Catholic Church. To them, birth control was bound to a deep moral crisis in society. Yet the number of users of birth control grew, and ideas about family size and women’s roles in society changed. Activists like Margaret Sanger (1883–1966) aided in the popularization of birth control, linking it to greater freedom for women. Sanger coined the term birth control in 1913 to replace the label of neo-Malthusianism. As the birth control movement became more popular, it attracted allies that began to reframe birth control as more than just fertility limitation. This is how the notion of birth control became associated with that of family planning by the 1930s.

Birth control acquired an additional political meaning in the 1950s with the Cold War. While population growth stabilized in Europe and North America, it accelerated in the so-called third world. The contraceptive pill emerged in this context and was promoted not only as a convenient contraceptive but also as a tool to lower population growth rates. Devised by the biologist Gregory Pincus (1903–1967) with funds from philanthropist Katharine McCormick (1875–1967) and Sanger’s support, and marketed by G. D. Searle, the pill became the most popular form of birth control by 1965 in the United States.

During the late 1960s, the prospect of misery, anarchy, and socialist advances in the third world led to international development policies like the U.S. Alliance for Progress and the involvement of philanthropies like the Rockefeller Foundation in population control programs. The latter were tied to the intervention of governments in the developing world, some of which applied policies throughout the 1960s, 1970s, and 1980s to quickly lower population growth rates to match objectives set by medical and social science experts in industrialized nations. As was evident following the United Nations World Population Conference of 1974 in Bucharest, however, third world nations often suspected that population control programs were implemented only for the benefit of developed nations, while hurting the interests of the third world and failing to address the root causes of poverty and inequality. Third world nations also claimed often that population control programs sometimes conflicted with local and personal beliefs about the worth of individual births. Today, with the exception of China’s “one-child policy,” instituted in 1978, birth control programs in most countries have retreated from the aggressive promotion of some methods in favor of voluntarism, informed choice of contraceptives, sex education, and the insertion of birth control provisions within broader systems for health care delivery, particularly maternal and infant health. This trend began as early as the mid-1960s. Yet, even now, as in the eighteenth century, the free choices and additional services implied in family planning are part of a complex process involving individual decisions, social values, and material constraints.

**Birth of a Nation**

D. W. Griffith’s film *Birth of a Nation* appeared in 1915 to the outrage and dismay of the National Association for the Advancement of Colored People and other supporters of black Americans’ citizenship rights. The film was an adaptation of Thomas Dixon’s novels *The Clansman* (1905)—the film’s original title—and, to a lesser extent, *The Leopard’s Spots* (1902), which, along with *The Traitor* (1907), formed Dixon’s self-consciously white supremacist trilogy. Following Dixon’s novels, the film advanced a relentlessly proslavery narrative of the slaveholding South, the Civil War, and especially Reconstruction. It depicted blacks either as simple and ignorant ciphers or as brutish fiends driven by compulsions to put on airs and accost white women. Abolitionists and whites aligned with the freedpeople after the Civil War appeared as irresponsibly naive, venal, or malevolent, motivated by greed or base desires to humiliate and destroy the South through the agency of black dupes. In this depiction, black enfranchisement was a travesty that enabled degenerate whites and incompetent blacks to dominate the formerly secessionist South’s governance and to impose a corrupt tyranny on the region’s whites.

The interpretation put forward in Dixon’s novels and Griffith’s film was propagated aggressively by southern elites during the years between their successful campaign to disfranchise blacks and many poor whites and the onset of the First World War. This interpretation became scholarly historical orthodoxy, in no small measure through the work of Columbia University historian William A. Dunning. Dunning’s book, *Reconstruction, Political and Economic: 1865–1877* (1907), systematized the southern white supremacist view and gave it the appearance of academic objectivity. Instructively, epigraphs from the book are interspersed throughout the film, which stands as an epic cultural expression of the Dunning school’s line. In this regard, the film, along with Dixon’s novels, is also the direct lineal ancestor of Margaret Mitchell’s *Gone with the Wind* and the film adapted from it. In addition to striking structural parallels between the two films’ narratives, Mitchell had been an avid reader of Dixon’s novels, and he wrote her a gushing fan letter on her novel’s publication.

*Birth of a Nation* has been widely celebrated for its technical cinematic innovations. Griffith’s film is typically credited with pioneering use of such techniques as deep focus, the jump cut, and facial close-ups. Its large-scale battle scenes were also unprecedented. Its use of seemingly authentic daguerreotypes that shifted into live action also fed an illusion of historical accuracy. For these and other such accomplishments—as well, presumably, as its popularity at the box office (it was by far the highest grossing film of its era)—the American Film Institute lists Griffith’s melodrama as one of the most important films of the twentieth century. However, although the film’s technical achievements no doubt contributed to its visibility when it was released, its inflammatory politics are what generated the strongest reaction. *Birth of a Nation’s* opening provoked riots in many cities, as groups of whites were moved by the film, or took the occasion of its screening, to rampage against blacks. The film was banned in several other cities, including Chicago, and in the state of Ohio.

The film’s story line is a conventional, heavy-handed romance that is a thinly allegorical template for projecting southern elites’ vision of sectional reconciliation on explicitly white supremacist grounds. The plot follows two upper-status families—the northern Stonemans and the southern Camerons—from the late antebellum period through Reconstruction. The northern family’s patriarch is modeled to evoke Pennsylvania Radical Republican Thaddeus Stevens; the southern family embodies the sympathetic stereotype of a planter class defined by grand manners and genteel paternalism. The families are linked socially before the Civil War, and one of the Stoneman sons falls in love with a Cameron daughter on a visit to the latter family’s antebellum plantation. However, the war divides the two families and disrupts the potential romance. Both families lose sons in the war, which also further entwines their fates. A Cameron son is wounded and captured in battle and, in a Union hospital, encounters and falls in love with Stoneman’s daughter, who is volunteering as a nurse. In this narrative love thus transcends and is disrupted by the sectional conflict, which brings the film’s first part to a close.

Establishment of the romantic story line drives *Birth of a Nation*’s first part. In the film’s second part, shown after an intermission, the romance becomes a platform for an equally sentimentalized narrative of the respectable white South’s suffering under Reconstruction. This account is a purely partisan fantasy of the years after the Civil War. Conniving and malcontented mulattoes aspire to reach above their station, ultimately through intermarriage. Ignorant and brutal blacks make a travesty of the exercise of government. They and their base white allies reduce patient, suffering upper-class white southerners to poverty and heap one indignity after another upon them. Tellingly, in Griffith’s narrative, having to extend the routine civilities of social etiquette to blacks, acknowledge their equal citizenship, and confront their unwanted sexual advances are interchangeable affronts, and the first two inevitably lead to the third.

The melodramatic story line feeds this linkage. In one of the film’s more incendiary sequences, Flora, the Cameron’s spirited but virginal daughter—whose very name identifies her as a flower of southern womanhood—is mortified by a proposal of marriage from Gus, a Union soldier and former slave. She flees hysterically with Gus in
pursuit and leaps to her death to preserve her honor. Gus, whom Griffith describes as “a renegade, a product of the vicious doctrines spread by the carpetbaggers,” is captured and summarily lynched by the Ku Klux Klan. The Klan subsequently rides to the rescue of the beleaguered whites, rises to overthrow the Reconstruction tyranny, and forcibly disfranchises blacks. This resolves to a happy ending that unites the Cameron and Stoneman lovers and restores the natural social order to the South. Gus’s character was portrayed by a white actor in blackface, as were all the black characters who had physical contact with whites. Thus the film featured both black and white actors playing black characters.

Griffith’s melodrama, by grounding its Reconstruction narrative in the personal story of the Cameron and Stoneman families, conveniently sidesteps the potentially troublesome issue that disfranchisement violated black southerners’ constitutional rights under the Fifteenth Amendment. Just as the first part of the film’s depiction of the South Carolina plantation world gives no hint that slavery was fundamentally a system of coerced labor, the second part obscures the fact that the foundation of post–Civil War southern politics was a struggle between the freedpeople and their allies to craft a social order based on free labor and equal citizenship and the dominant planter class’s desire to restore a social and economic system as near as possible to the slave society that Union victory had destroyed.

Instead, Birth of a Nation propounds a view in which race is the single fulcrum of politics, the authentic basis of identity and allegiance. Such views were prevalent among Americans of all sorts during the early twentieth century, perhaps more so than at any other time before or since. Putatively scientific race theories purported to link human capacities, including the capacity for democratic government, hierarchically to racial classification. Several features of the social landscape at the time helped to give such views of the bases and significance of human difference presumptive credibility, particularly among opinion-shaping elites. Upper-status reactions against labor and populist insurgencies fueled a political conservatism readily open to arguments that manifest social inequalities were rooted in immutable natural differences. Advocates of imperialist expansion also asserted unabashedly racial arguments, typically adducing an irrepressible Anglo-Saxon or Teutonic racial spirit for conquest, along with a racialized notion of American providential entitlement, to justify international adventurism in Latin America and the Pacific. Especially in the North and Pacific West, intensifying anxiety about increasing immigration from the margins of Europe and Asia further propelled racist discourse, as race scientists and courts sought to determine whether immigrants originated from groups capable of assimilating to “American” civilization. Fears concerning immigrants’ dilution of nativist American cultural authority also contributed to a growing conviction among elites that voting and political participation should be seen not as a right but as a privilege, that fitness to vote should be proven, not assumed, and that the respectable classes are the natural stewards of the polity.

The political and ideological environment that took shape during that period also supported those tendencies within the national Republican Party and northern opinion that argued for retreat from aggressive support for the southern freedpeople’s rights and for sectional reconciliation on lines that favored the southern planter and merchant class. That sentiment underwrote the withdrawal of federal military occupation in 1877 and a shift in the courts’ willingness over the ensuing decades to protect blacks’ rights. In its ruling in the 1883 Civil Rights Cases, the U.S. Supreme Court invalidated the 1875 Civil Rights Act, and in its 1896 Plessy v. Ferguson ruling the Court legitimized legally imposed racial segregation, enunciating the infamous “separate but equal” doctrine. Residual northern liberal inclinations to defend southern blacks were further assuaged by Booker T. Washington’s emergence as a prominent voice of black acquiescence to white supremacy in the South and his endorsement of blacks’ expulsion from the region’s civic life.

Griffith’s film reflected and exploited this environment. In a clear effort to appeal to northern sensibilities, the film’s first part ends with a mournful depiction of the assassinated Abraham Lincoln as a kindly figure who would not have permitted the white South to be abused. The fabrication of Austin Stoneman as a stand-in for Thaddeus Stevens similarly rationalizes sectional reconciliation. The real Stevens never wavered in his Radical Republican convictions, to the point that he insisted on being buried in a black cemetery. Griffith’s fictional character, on the other hand, abjures his support of blacks’ rights once he is confronted by his mulatto protégé’s attempt to marry his daughter. The film’s message is clear: Decent northerners who had been abolitionists were misguided, and even the staunchest of them would come to see the need for white supremacy. This message drives the film’s climax. In building to the crescendo of the Klan’s rescue, the fleeing white victims are given refuge in a rude shack occupied by former Union soldiers who had remained in South Carolina after the war, living as modest yeomen. The northern men respond to the situation from the race loyalty that unites Americans from both sections, and they take up arms to fend off the pursuing black militia. This, then, is the definitively racial basis on which Birth of a Nation proposes sectional reconciliation. As Griffith narrates, “The former enemies of North and South are united again in common defence [sic] of their Aryan birthright.”
Instructively, the film quotes Woodrow Wilson, then president of the United States, explaining that “The white men were roused by mere instinct of self-preservation … until at last there had sprung into existence a great Ku Klux Klan, a veritable empire of the South to protect the Southern country” (Wilson 1902, pp. 59–60). Wilson had been Thomas Dixon's classmate at Johns Hopkins University and enjoyed a private screening of Birth of a Nation at the White House. Wilson embodied the victory of the white supremacist politics Birth of a Nation advocates. A native southerner, he was at different times president of Princeton University and governor of New Jersey, as well as president of both the American Political Science Association and the American Historical Association, as Dunning had been some years before him. Wilson's scholarly writing and his public actions were shaped fundamentally by the race theories of the day and the presumptions of white supremacist ideology in particular. As president of Princeton, he sought to impose white-only admissions; as president of the United States, he more consequentially imposed full racial segregation on the District of Columbia and drove blacks from federal employment.

ATTITUDES TOWARD OUT-OF-WEDLOCK BIRTH IN THE UNITED STATES: HISTORICAL TRAJECTORY

The history of out-of-wedlock childbearing in the United States must be understood in the context of the racialized social, economic, and political structures that both preceded and followed independence. Nonmarital birth was an integral part of the slave system: White men married white women but entered into non-legal unions with women who were black or “colored.” While policies varied over time, until the early-to-mid-nineteenth century slave marriages were rarely allowed.

For the free and white population in colonial America, “bastardy” was considered a sin. While the notion that out-of-wedlock childbearing constitutes a moral failure never totally disappeared, during the eighteenth and early nineteenth centuries, nonmarital births increasingly came to be framed in terms of the economic burdens borne by communities forced to support fatherless children. By the end of the nineteenth and beginning of the twentieth century, public discourse, at least regarding white women, shifted from concern with “fallen women” (a pejorative moral category) to concern with “ruined girls” (an innocent population deserving of help). Progressive reformers understood that out-of-wedlock childbearing was a product as well as a cause of social disorder, and thus advocated sex education and better wages for women so that women would be less susceptible to the sexual advances of wealthy men.

The belief that unmarried mothers are at fault for their situation took on new life in the 1920s as experts began treating out-of-wedlock childbearing as “sex delinquency.” Using a new language of psychology and the unconscious, authorities diagnosed sexually active girls as unable to govern their impulses, and growing numbers of young women were sent into the newly created juvenile justice system. Throughout the twentieth century and into the twenty-first, the policy of incarcerating women because of sexual crimes (e.g., prostitution) has continued.

Intertwined moral and economic discourses reached new levels of codification when Congress passed the 1996 welfare reform known as the Personal Responsibility Act. The Act opens by proclaiming that, “Marriage is the foundation of a successful society,” and goes on to link various issues—teenage pregnancy, out-of-wedlock births, children raised in single-parent homes, and fathers who fail to pay child support—to high rates of violent crime, children with low cognitive skills, and other highly negative putative outcomes. According to Sharon Hays,

a reading of this statement of the law’s intent would lead one to believe that the problem of poverty itself is the direct result of failures to live up to the family ideal…. Single mothers on welfare are effectively punished for having children out of wedlock or for getting divorced. The punishment they face is being forced to manage on their own with low-wage work. [The Act sets a five-year lifetime limit for public aid regardless of need and a two-year limit for finding full-time employment]. (2004, pp. 17–18)

Race has continued to play a key role in attitudes and policies toward out-of-wedlock birth in the United States. Criticism of high rates of single-mother families often seems to be thinly disguised criticism of black single mothers, who are variously portrayed as sexually promiscuous, addicted to drugs, or out to “cheat the system” by having more babies for the state to support. Kenneth J. Neubeck and Noel A. Cazenave coined the term “welfare racism” to describe the stereotyped discourse and discriminatory programming associated with the welfare system: “Today, the words welfare mother evoke one of the most powerful racialized cultural icons in contemporary U.S. society” (2001, p. 3).

In the last decades of the twentieth century, “Fathers’ Rights” organizations and evangelical Christian groups have been vocal in asserting that female-headed families are psychologically and socially pathological and that children raised without their fathers are more likely to fail in school, use drugs, and end up in jail. Sociological studies tend not to support this view. The absence of the father does not have a significant impact on the psychological well-being of either daughters or sons. More important than physical presence or absence is how children perceive their relationships with their parents (Wenk et al. 1994). Moreover, given the high divorce rates in the United States, children born to a married mother and father have no guarantee of growing up with their two biological parents. In fact, studies show that unwed U.S. fathers actually see their children more often than do divorced fathers who have remarried.

RATES OF OUT-OF-WEDLOCK BIRTHS IN THE UNITED STATES AND EUROPE

In the United States in 1970, 10.7 percent of all live births were to non-married women. The percent rose throughout the 1980s, leveling out at about 32 to 33 percent in the mid-1990s, and going up to 34.6 percent in 2003. The biggest increase was among white women for whom rates rose from 5.5 percent in 1970 to 29.4 percent in 2003. For black women, the percent of out-of-wedlock births doubled from 37.5 percent in 1970 to 68.2 percent in 2003. Among Hispanic women, the rate increased from 23.6 percent in 1980 to 45 percent in 2003.
Over these years, the age distribution of out-of-wedlock childbearing indicates a shift toward purposeful out-of-wedlock childbearing among more mature women. In 1970, 50.1 percent of live births to unmarried women were to women under the age of twenty, 31.8 percent to women twenty-one to twenty-four, and 18.1 percent to women twenty-five and older. By 2003 only 24.3 percent of out-of-wedlock births were to women under the age of twenty, while 38.8 percent were to women twenty-one to twenty-four, and 36.9 percent to women twenty-five and older.

In 2004 nearly a third of the 4.8 million babies born in the European Union were born out-of-wedlock. The phenomenon is particularly noticeable in Scandinavia and the three Baltic member-states with a ratio of 57.8 percent in Estonia, 55.4 percent in Sweden, 45.4 percent in Denmark, and 45.3 percent in Latvia. The lowest levels of children born out of wedlock are in southern Europe with 3.3 percent in Cyprus, 4.9 percent in Greece, and 14.9 percent in Italy.

It should be noted that in statistics from Europe and the United States, the term out-of-wedlock means only that the newborn’s parents are not registered with the government as “married”; it does not mean that the child is being raised only by its mother. In the Scandinavian countries, in particular, nonmarital births generally take place in long-term committed relationships to parents uninterested in church weddings and not in need of government-issued marriage certificates in order to have pensions or other benefits. Americans too are much more likely than ever before to bear children in reasonably stable partnerships—including same-sex partnerships—that are not legally recognized marriages.

EXPLAINING NONMARITAL BIRTHS
Efforts to explain rates of out-of-wedlock births in the United States have been characterized more by sentiment than scientific evidence. Conservatives typically attribute the increase to overly generous federal welfare benefits that encourage poor women to have children. However, a comparison of out-of-wedlock birth rates with changes in welfare benefits over time does not show a correlation between the two. Liberals have tended to attribute the increase to declines in the marriageability of black men due to shortages of jobs for less-educated men, the disproportionate deaths of black men in the military, and high rates of incarceration of young black men. Demographic studies indicate, however, that only a small percentage of the decline in black marriage rates can be explained by the shrinking of the pool of eligible men.

A popular set of explanations maintains that single parenthood has increased because of changes in attitudes toward sexuality. While some analysts blame sex education in schools for encouraging early sexual activity, others advocate the benefits of sex education in helping teens make informed decisions regarding sexuality and contraception. Still others argue that the legalization of abortion and increased availability of contraception (birth control pills) give women tools to control the number and timing of their children. These tools empower women to make choices regarding childbearing and curb customs such as “shotgun marriages” that traditionally reduced rates of out-of-wedlock births (though not of out-of-wedlock conception).

**BLACK ARTS MOVEMENT**

Characterized by African American poet, activist, and theorist Larry Neal as “the aesthetic sister of the Black Power concept” (Neal 1989, p. 62), the Black Arts Movement (BAM) is one of the most controversial cultural movements of the modern era due to its racialist intellectual bases; its commitment to economic, political, and cultural autonomy for African America; and its overtly revolutionary intentions. It carried through the African American educator and writer W. E. B. Du Bois’s 1926 call for art “about us,” “by us,” “for us,” and “near us” (Du Bois 1926, pp. 134–136). It was, in poet Kalamu ya Salaam’s words, “the only American literary movement to advance ‘social engagement’ as a sine qua non of its aesthetic” (Salaam 1997, p. 70). Initiated in the early 1960s, though rooted in a radical tradition dating back at least to the Haitian Revolution of 1791, it flourished, suffered setbacks in the mid-1970s from federal government harassment via the FBI’s counterintelligence program and from economic downturn, and continues in the early twenty-first century. Such continuity challenges the African American scholar Henry Louis Gates Jr.’s contention that the BAM was the “shortest and least successful” cultural movement in African American history (Gates Jr. 1994, pp. 74–75).

Although other media such as painting, poetry, dance, and music were significant, theater and drama played a preeminent role due to their communal nature, focus on transformation, and institutional, organizational, and economic demands. Neal writes, “Theater is potentially the most social of all the arts. It is an integral part of the socializing process” (Neal 1989, p. 68). Especially influential were Amiri Baraka’s *Dutchman* (1964) and the institution he co-founded in 1965, Harlem’s Black Arts Repertory Theatre/School. This focus on aesthetic innovation within institutional development reflects the thinking of social scientists such as John Henrik Clarke, C. Eric Lincoln, and Harold Cruse. A generation of artists was fostered in organizations such as BLKARTSWEST, the African Commune of Bad Relevant Artists, Spirit House, and the New Lafayette Theatre, and in the many black studies programs created in universities and colleges across the United States in part due to the actions of BAM artists and intellectuals.

Other significant influences can be identified. First, within the movement there was a focus on popular and folk culture via Du Bois (1868–1963), the African American educator and critic Alain Locke (1886–1954), the Italian Marxist theorist Antonio Gramsci (1891–1937), the black Trinidadian historian and activist C. L. R. James (1901–1989), the African American writer and ethnographer Zora Neale Hurston (1903–1960), and the Chinese theorist of cultural warfare Mao Zedong (1893–1976). The Black Muslim leader Malcolm X (1925–1965) was perhaps the most influential in the formation of the movement: “Our cultural revolution must be the means of bringing us closer to our African brothers and sisters” (Malcolm X 1970, p. 427). This is a matter of content, but also production conditions—where, by whom, and for whom the art is created. It is also a matter of technique: In *Performing Blackness: Enactments of African-American Modernism* (2000, p. 28), Kimberly Benston argued for the primacy of methexis (“communal helping-out of the action by all assembled”) over mimesis (“the representation of an action”). In practice, this meant: (1) participatory works such as the National Black Theatre’s *A Revival! Change! Love! Organize!* (1969) or Sonia Sanchez’s “a/coltrane/poem” (1970), which supplies directions such as “sing loud & long with feeling” (Sanchez 1991, p. 184); (2) a call to action, as in the agitation-propaganda poetry of Don L. Lee or Nikki Giovanni or the “revolutionary commercials” of Ben Caldwell; and (3) invitation to the audience to discuss and criticize, most notably the public discussion panel convened at the New Lafayette Theatre in the fall of 1968 to discuss its controversial production of Ed Bullins’s *We Righteous Bombers*, a play that scathingly critiques those who advocate revolutionary violence.

A second influence was radical theology, the assumption being that the most invidious effect of slavery and colonialism was spiritual. As James T. Stewart asserted, “[E]xisting white paradigms or models do not correspond to the realities of Black existence. It is imperative that we construct models with different basic assumptions” (Stewart 1968, p. 3). Ritual dominated the stages and
periodicals of black theater in the late 1960s. Religious content was a constant in the visual arts, as in Margo Humphrey’s Afrocentric take on *The Last Supper, The Last Bar-B-Que* (1988–1989). That said, religion was not universally appreciated; Caldwell showed no sympathy for the theologically minded in *Prayer Meeting, or, The First Militant Minister* (1969). It depicts a hilarious bit of subterfuge by a quick-on-his-feet burglar and a hopelessly gullible liberal preacher who mistakes the intruder for God. Likewise, Joyce Green criticized her compatriots—especially men—for their tendency to cloak misogyny in metaphysical vestments.

Finally, music—popular and avant-garde—enabled the dynamic of tradition and innovation called for by cultural revolutionaries such as Amilcar Cabral, Kwame Nkrumah, Mao, and Malcolm X. Blues, rhythm-and-blues, gospel music, and jazz were considered the “key,” as Neal put it, to expanding the movement’s connections to local, national, and international currents (Neal 1968, p. 653). Studied with an eye to their aesthetic, conceptual, and communal dimensions, traditions such as the blues were understood to be modes of critical discourse whose contours could be mapped onto other aesthetic and critical-theoretical forms.

Too often, as Cedric Robinson demonstrated in his *Black Marxism: The Making of the Black Radical Tradition* (1983), the continuity of the black radical tradition has been obscured. As in music, such continuity exists not only between BAM artists and critics and their forebears, but also to the post-BAM generation. To adequately account for the success or failure of the BAM, one must understand it as merely the epiphenomenon of a history that preceded it and continues in the twenty-first century.

**BLACK CONSERVATISM**

Despite its seeming novelty and the monolithic nature of its contemporary precepts, black conservatism has a history that reaches back to at least the late eighteenth century and is capacious enough to include figures as diverse as Frederick Douglass, Zora Neale Hurston, Malcolm X, and Bill Cosby. The tradition, often but not exclusively peopled by the middle class, constellates around three key features. The first is a deep desire for racial autonomy that, in being effected, would ultimately result in personal independence. In short, black conservatives take a citizen’s constitutional prerogative to pursue happiness very seriously. The second is the commitment to obliterate race as a limiting factor or indexical feature of human achievement. Toward this end, black conservatives are quick to repudiate theses that pathologize African American life, producing a defensive posture that once impelled Ralph Ellison to famously question, “Can a people live and develop for over 300 years simply by reacting to white racism?” (Ellison 1995, p. 339). The third is a compulsion toward social respectability, one that includes obedience to society’s laws, a hearty work ethic, religious piety, family values, sexual morality, and a kind of “role model” politics that if unable to exemplify admirable black behavior to other blacks, would at least prevent the race from being
embarrassed in the eyes of the (white) American public. This ethos not only resulted in Rosa Parks rather than the impoverished, less refined, single mother Claudette Colvin becoming the cause célèbre of the 1955 Montgomery bus boycott; it also at times has inspired impassioned jeremiads that scold the black masses for behavior conservatives deem dissolute and licentious. This policing practice has also at times kept an unnecessary harness on more demonstrative resistances to U.S. racism.

For conceptual purposes, the tradition, like most other American phenomena, can be divided into its modern and postmodern versions, with the assassination of Martin Luther King Jr. marking the decisive break. Black conservatism of the past pragmatically accepted racial segregation as a fact of American life and sought to thrive despite its imposed social constraints. Consequently, there is a manifest enthusiasm toward exclusively black institutions. Starting with the accomplished shipbuilder James Forten and through the agrarian wizardry of Booker T. Washington, the marketing genius of Madame C. J. Walker, and the urban entrepreneurialism of Elijah Muhammad, black conservatism saw racially homogeneous business relations, education, and religious life as an existential and economic antidote to their social marginalization, thus creating the irony that the lion’s share of this epoch’s black conservative politics proffered radical opposition to the will of the American mainstream.

In distinction from this strain, postmodern conservatism is a child conceived in the political atmosphere following the putative fall of legalized segregation and thus does not find its grounding in institutions that organically emerged from a discrete black body politic. Instead its birth site may be located in the strategic conference rooms of the Republican National Congress in 1968 when party leaders founded Heritage Groups (later to become the Heritage Foundation) to increase minority membership among its ranks. More beholden to American individualism and noninterventionist government than their predecessors, theorists such as Thomas Sowell, Shelby Steele, Alan Keyes, and Angela McGlowan find in the passing of civil rights legislation in the 1960s the indisputable end of American racism. With race no longer impeding black accomplishment, these commentators encourage African Americans to defrock themselves of long-standing resentments about discrimination and embrace what they see as an existential and economic antidote to their social marginalization, thus creating the irony that the lion’s share of this epoch’s black conservative politics proffered radical opposition to the will of the American mainstream.

Bent on preventing past black victimization from entering contemporary discussions about social justice, today’s black conservatives saturate the public discussion with diatribes about black victimization in the present, which they believe come in the form of government welfare programs that allegedly enfeeble black ambition and limit black achievement. They claim that whatever black failure persists does so because of the dependent, lower class culture that such programs perpetuate.

This generation of black conservatives has been criticized for silencing their outrage toward blatant gestures of racism, accommodating the avarice of neoliberal economics, and supporting the neonationalism that underwrites the aggressions of contemporary U.S. imperialism. Though officeholding conservatives have only been tepidly responsive to the appeals of their black supporters (Republican administrations have continued to tolerate affirmative action programs), the latter are viewed by Americans with both skepticism and seriousness because of the largesse they command from powerful mainstream organizations such as the Heritage Foundation, the Hoover Institute, and the Fox News Corporation.

BLACK LIBERALISM

While the term *black liberalism* is often seen as a pejorative favored by black conservatives and black nationalists, it is better understood as part of the epistemology of black political thought. In his 2001 work on contemporary black political ideologies, Michael Dawson distinguishes black liberals from black nationalists and black Marxists by the liberals’ belief in race-neutral constitutional order, liberal democracy, and capitalism. Dawson sees the tension black liberals face in trying to avoid the pessimism of black nationalists and black Marxists, who believe that liberal democracies or capitalism cannot be free of the implicit racist constructs of the white hierarchy. He defines black liberals as unique from white liberals in the black liberal belief that the liberal construct of equal rights includes economic, social, and political egalitarianism; and that America will be better if it can fulfill that egalitarian ideal for blacks. Put succinctly, Dawson quotes Malcolm X to say that black liberals have “a version of freedom larger than America’s prepared to accept” (p. 239).

In Dawson’s view, black liberals see racism as a potent force that is contradictory to and independent of liberal democracy and capitalism. Black nationalists believe that liberal democracies, born at a time of European colonialism and American slavery, not only fail to handle the contradiction between liberalism and colonial subjugation and slavery, but also implicitly incorporate the contradiction by enshrining racial hierarchies. Black Marxists see capitalism as inherently racist, based on models of capitalist exploitation.

W. Avon Drake (1991) offers another perspective, contrasting black liberals with social democrats. In Avon’s view, black liberals see racism as the primary impediment to black social progress, while social democrats stress class differences, with neither seeing either liberal democracy or capitalism as inherently racist. Social democrats see impediments to blacks as based on differences in class: Racial disparities are viewed primarily as economic class disparities. Thus programs designed to address poverty and issues of inequality are seen as more useful than programs aimed directly at racial disparities. Proponents of black social democracy include Abram Harris and, later, William J. Wilson.

The major triumphs of black liberalism include the 1954 Supreme Court decision in *Brown v. Board of Education*, the Civil Rights Act of 1964, and the Voting Rights Act of 1965. Research shows that these policies dramatically reduced racial income inequality in the southern United States (McCrone and Hardy 1978; Donohue and Heckman 1991). In 1965 the poverty rate for black children stood at 65.6 percent and fell to 39.6 percent by 1969. Principle architects of black liberalism include W. E. B. Du Bois in his earlier writings, Charles Houston, Thurgood Marshall, Martin Luther King Jr., and A. Philip Randolph.

Black liberalism has faced several challenges. The rise of the American conservative movement and the dominance of conservative ideology on the national level put black liberals at odds with the American political establishment. Cornel West (1994) has pointed out that the crisis for black liberalism has been its inability to handle the increase in economic inequality resulting from the deindustrialization of the U.S. economy. The poverty rate for black children remained above 40 percent from 1975 to 1992, rising as high as 47.3 percent in 1982. *Crisis* magazine, the official organ of the NAACP, pointed to an earlier conflict addressed by black liberalism, when between 1933 and 1953—from the time of the New Deal to the *Brown* decision—the fruits of the white liberal agenda in the New Deal excluded the black community (Anderson 1980).

The conservative challenge to black liberalism rests on one of three arguments: (1) blacks have developed a pathological culture in opposition to mainstream culture that fails to reward the elements needed to succeed in a capitalist system; (2) blacks are inherently inferior, an argument based on a genetic definition of race; (3) blacks for various reasons of history and culture lack the requisite skills to succeed in a capitalist system because market forces make discrimination in the marketplace of minimal importance. On the basis of these arguments, government intervention to combat racism is seen as an unwarranted intrusion of the government into the marketplace. (William Darity and Patrick Mason refute these points in their 1998 work, arguing that the evidence fails to support the belief that blacks have a pathologic culture and that discrimination within the marketplace is substantial.)

Black liberals view blacks as “liberal man”—rational in the liberal sense of acting consistently to advance black well-being and economic success (as opposed to irrational, or pathological, failing to act in their economic interests). Black liberals explain racial disparities in economic and political life as the result of racism and, in a nod to black nationalists and Marxists, posit that there are institutional barriers born of the implicit racist pact that allows for legal segregation and slavery in a liberal democracy. The conservative argument views blacks as not rational, as making choices not in their best interest. The resulting caricature by conservatives is that black liberals portray blacks as victims, and the term *black liberal* has often come to be defined by this pejorative view. Conservatives also argue that the black liberal agenda creates a dependency on government, which is what makes black culture pathological and is the real source of racial disparities in economic and political life.

BLACK MIDDLE CLASS

In the United States, where blacks have comprised a sizable minority in relation to a white majority, and in South Africa, where blacks have comprised a considerable majority in relation to a white minority, the growth of a black middle class has been regarded as an important benchmark for blacks' social and economic standing. A growing black middle class would seem, at least, to indicate improving social mobility, greater affluence, and expanded life chances for blacks.

In fact, the social science literature suggests that middle-class status, with all that it promises, is precarious for those blacks who have achieved it, and still out of reach for many others. As members of a minority group, middle-class blacks face historical and persistent marginalization, discrimination, and racism; consequently, their experience differs from that of the white middle class. Scholars have struggled to decide who among minority black populations should actually be considered middle class. Nevertheless, studies dedicated to defining and describing the black middle class confirm that inequities persist between blacks and whites in the United States and South Africa, as well as between middle-class blacks and poor blacks, despite the dismantling of legal structures that discriminate against blacks.

UNITED STATES

Prior to the civil rights movement in the United States, a small black elite emerged that often was defined by skin color—that is, lighter-skinned blacks had greater opportunities for social advancement than darker-skinned blacks. This elite has been called the “black bourgeoisie” (the title of a controversial book by E. F. Frazier) and the “old black middle class” (a term used by the academic Bart Landry). It was associated with the educated strata of the black population, which W. E. B. Du Bois hoped would produce a “talented tenth” to serve as intellectual leaders for American blacks. Members of this group typically engaged in professional services to the black community, holding occupations such as teacher, social worker, pastor, mortician, and, occasionally, doctor or lawyer, as well as business owner. The success of these business owners was contingent in part on the existence of a market protected by segregation. Because they were excluded from working with or for whites, this “old” black middle class relied on the limited resources of black patrons and enjoyed only limited social mobility.

The civil rights era gave rise to a “new” black middle class. Some scholars have traced the origins of the black middle class to an earlier period, when restrictions on immigration (especially the Immigration Act of 1924) were introduced after World War I (1914–1918). These restrictions created opportunities for black workers to move in great numbers from the agricultural economy of the South to the industrial economy of the North. However, the scholarly literature generally attributes the growth of the black middle class chiefly to increased economic prosperity following World War II (1939–1945); to improved job opportunities for blacks after civil rights, especially in the public sector; and to the expanding economy of the 1960s.

Defining the Black Middle Class Scholars have struggled to define the black middle class. The most commonly employed criteria for membership have been income, education, occupation, and wealth. These measures are used either in combination or independently. The difficulty with using these measures to define the black middle class is that pronounced disparities between blacks and whites exist for all these variables. A black middle class defined by the middle range of black incomes, for instance, is not comparable to a white middle class defined by the middle range of white incomes. The 2000 U.S. census reported that whereas half of all black households have incomes of
$29,423 or more (based on 1999 dollars), the corresponding figure for white households is $44,687, a difference of more than $15,000. In addition, scholars have disagreed about which occupations should be defined as “middle class”; opinions range from a strictly white-collar criterion to a less restrictive one that includes protective services, skilled craftsmen, and clerical and sales workers. Furthermore, discrimination in the workplace prevents occupational prestige from being a reliable marker of blacks’ social positions, especially the social position of middle-class blacks. Several scholars have proposed that lifestyle, values, and behaviors are much more meaningful measures of black middle-class experience than income, education, occupation, and wealth. Other social scientists have questioned whether it is appropriate to classify blacks as members of the middle class at all, given the pronounced disparities between the black and white middle classes, as well as broader problems with defining class.

**Describing Black Middle-Class Experience** An extensive literature characterizes the black middle class in terms of the inequities that middle-class blacks experience in relation to middle-class whites. These inequities include unequal residential patterns, occupational profiles, wages and wealth, and family structures. Middle-class blacks live in less socioeconomically attractive neighborhoods, close to the black poor; this phenomenon, dubbed *racial residential segregation*, may prevent social mobility. Middle-class blacks work disproportionately in the public sector, especially in city, state, and federal government. Of blacks who work in the private sector, the majority are pigeonholed into positions where they interact chiefly with black patrons.

Although middle-class blacks have moved increasingly into white-collar occupations, they have not received wages comparable to their white counterparts: In the closing decades of the twentieth century, blacks made 70 percent of what their white counterparts made. One consequence of this disparity in wages is that blacks receive less of a financial return on their personal investments in education than do whites. One study found that the black/white disparity is even more pronounced for men with more education (Tomaskovic-Devey, Thomas, and Johnson 2005). The black/white disparity is evident when comparing not only wages (income) but also wealth (assets). Home ownership is a primary means for individuals to establish and maintain their wealth status, but black home ownership lags behind white home ownership. In 2000, 46 percent of blacks and 71 percent of whites were homeowners. A few years earlier, a study reported that blacks had only 15 percent of the wealth that their white counterparts had. Thus, although the cohort whom scholars call the black middle class has grown historically, members of that cohort remain at a disadvantage compared to their white counterparts.

Related to labor and wealth are three characteristics of the black middle-class family structure that make that middle-class status precarious. First, black wives have to participate in the labor force to secure and maintain middle-class status for their families. Second, wealth disparities relative to whites leave middle-class blacks with fewer assets to bequeath to the next generation. Third, middle-class blacks have an extended family structure that emphasizes their moral obligation and social responsibility to invest assets in the larger black underprivileged community. These factors contribute to continuing economic disadvantages for the black middle class in the United States as compared to the white middle class.

**SOUTH AFRICA** Apartheid had produced a South African black elite that was employed in—but confined to—serving a black clientele. Opportunities for social mobility expanded momentarily after the end of apartheid in the 1990s. On winning control of government in 1994, the African National Congress (ANC), guided by the National Democratic Revolution theory, set out to foster a black middle class. The ANC pursued this goal by promoting growth and redistribution of wealth and by transforming social institutions and economies through “equality employment” and “Black Economic Empowerment.” These developments (which were similar to affirmative action programs in the United States) enabled South African blacks to move into the public sector. While some blacks gravitated to government employment, others obtained degrees and found work in the private sector.

Despite the new opportunities for blacks that opened in the post-apartheid period, scholars have remained concerned about the relatively small size of the black middle class and about growing gaps between the black middle class and the black poor. Although opinions vary as to size of the black middle class, the consensus is that this group is quite small relative to the larger population. Out of a total population of 44 million, the black middle class comprises somewhere between 2.5 to 3.6 million. Black employees in South Africa are highly unionized, a fact that both increases wages and improves work conditions; however, these benefits do not extend to poor unskilled blacks, who are prevented from unionizing and thus have greater difficulty in securing fair wages. As a result, though unionization has decreased inequality between whites and blacks, it has increased inequality between middle-class and poor blacks. South Africa presents the same problem seen in the United States: The black middle class is making modest strides toward parity with the white middle class.
class, whereas a class of impoverished blacks falls further and further behind.

BLACK NATIONALISM

In the strictest meaning of the term, black nationalism refers to those ideas and movements that are associated with the quest to achieve separate statehood for African Americans. The goal of statehood was especially important during the “classical” period of black nationalism—the time of Marcus Garvey (the 1920s) and of the early activists who preceded him. During the “modern” period, especially after World War II, black nationalism encompasses more broadly both those who favored true political sovereignty through separate statehood, and those who favored more modest goals like black administration of vital private and public institutions—the latter being the common cause of those who invoked the slogan of “Black Power” after 1966. Black nationalism must always be understood in its historical context, therefore, as particular ideas and movements invariably bear the marks of their respective eras.

CLASSICAL BLACK NATIONALISM

Classical black nationalists advocated political sovereignty and they insisted that such a goal required the creation of a nation-state with clear geographical boundaries. There was not much support for this idea before the passage of the Fugitive Slave Act of 1850. Part of the Compromise of 1850, this act denied captured slaves (or those simply accused of being fugitive slaves) the right to a trial and granted marshals the power to force citizens to assist in the recapture of runaway slaves. It also prohibited testimony by those accused, and thus raised the possibility that free blacks could be captured into slavery. This was an era in which the U.S. political elite defined the meaning of citizenship in “white nationalist” terms. Justice Taney stated this perspective forcefully in the infamous 1857 Dred Scott case. Concerning the phrase “all men are created equal,” Justice Taney commented that “it [was] too clear for dispute that the enslaved African race [was] not intended to be included and formed no part of the people who framed this declaration.” The African race, Taney argued, had “no rights which the white man was bound to respect.” Until the eve of the Civil War, politicians worked to expand and secure rights for the majority of whites (males), while at the same time they increasingly restricted the rights of free blacks with prohibitions against intermarriage, rules that barred the migration of blacks to different states, and laws that denied suffrage and that even established formal segregation. Thus, by the mid-nineteenth century Martin Delany, James T. Holly, and others began to argue that black people should leave the United States for Canada, Haiti, or other destinations.

What set apart these “nationalists” from other black historical actors of the period were their positions on emigration and nation-building, not their views of culture. As Wilson Moses explains in his Golden Age of Black Nationalism (1978) and other writings, classical black nationalists were Christians, and they believed that Western civilization was the measure of progress when it came to letters, arts, commerce, and governance. All free black Americans of this period shared these views. It was not until after World War II that black (cultural) nationalists began to try to break entirely from Western convention.

Marcus Garvey founded the Universal Negro Improvement Association (UNIA) in 1918, and built the largest black nationalist movement in the history of the United States. The movement originated in Harlem, New York, and grew out of the social, economic, and political experience of native and foreign-born blacks of the period. Garvey’s nationalism was “classical” in the sense that his final goal was political autonomy, and he was Western in orientation. In terms of ideas and practice, however, the UNIA also reflected developments unique to its era. The 1920s was a period of heightened anticolonial, nationalis-
tic consciousness among many oppressed peoples of the world, and thus in tone, if not in substance, the arguments advanced by supporters of Garvey’s vision was akin to arguments against colonial domination seen in, say, Ireland or India—especially in the Caribbean region, where the UNIA established a number of chapters. The 1920s might also have represented the height of white American nationalism in the United States. The Ku Klux Klan peaked in membership (at several million), by defending “pure womanhood” and opposing immigration and all forms of labor activism. This was also the period when, in 1924, the U.S. government instituted immigration quotas that favored Northern Europeans over all others. In terms of membership numbers and visibility, the UNIA’s apex was congruent with the rise of white American nationalism of its time.

In terms of its program, the UNIA was conservative socially, economically, and politically. Although Garvey initially explained the ambitions of the organization in language that clearly reflected the influence of revolutionary (Bolshevik) thought, as well as anticolonialism, very quickly after the founding of the UNIA his message (in the United States) reflected conventional, even reactionary, thinking about race and political empowerment in the United States. Echoing conventional wisdom about the enduring significance of “racial” identity, Garvey argued for racial purity. While Garvey and his followers articulated a kind of racial chauvinism, a pride in black identity, that few had previously articulated, he nevertheless was reproducing the racist ideology of that period. After all, it was the Klan who argued most forcefully for racial purity. Starting with an organic view of racial identity—which ignored diversity among black people—Garvey eschewed talk of class struggle and union organization and argued for a strategy of building black businesses, believing the race would find redemption in the economic marketplace. The most prominent of the UNIA business ventures was the unsuccessful Black Star Line. Unlike the National Association for the Advancement of Colored People (NAACP), Garvey and the UNIA did not devote much effort toward expanding civil rights for blacks in the United States. In this respect, the organization foreshadowed the Nation of Islam, arguably the most successful black nationalist organization in the postwar period.

Garvey is known for his “back to Africa” philosophy, but his organization was working for selective emigration, not mass return. Garvey argued that full equality in the United States was illusory at best, and so he supported a “Negro Zionism.” Black people in the Western hemisphere, he argued, should support the creation of an African nation in the eastern hemisphere (his choice was Liberia); by ensuring the development of the Negro Zion, black people in the United States, the Caribbean, and Africa would elevate their status. This reasoning was similar to that of James T. Holly and others of the antebellum period.

Black nationalism must also be understood with a number of spectra in mind. Since the second decade of the twentieth century, there have been disagreements among nationalists on “social” issues like “racial purity,” and religious belief. There have also been differences in terms of economic philosophy—specifically whether black equality could be achieved under capitalism. Nationalists have differed over political tactics—for example, they have argued over whether black people could win emancipation through lobbying and electoral strategies or only through armed insurrection. During the 1920s, the UNIA vastly dwarfed another organization, the African Blood Brotherhood (ABB), which combined racial nationalism with a socialist critique of capitalism. The ABB’s founder, Cyril Briggs—a native of St. Kitts in the West Indies—argued that black people constituted a separate nation, but unlike Garvey he sought to establish political sovereignty by revolutionary means. The Fenian Irish Republican Brotherhood was the likely model for the ABB. At its peak, the organization claimed several thousand members. It was eventually absorbed by the Communist Party.

MODERN BLACK NATIONALISM

Of the “modern” black nationalist organizations operating in the postwar period, the National of Islam (NOI) has been the largest and most enduring. The Nation of Islam expanded in size and significance largely due to the efforts of one convert, Malcolm X. Born Malcolm Little, Malcolm X converted to Islam while in prison, abandoned his slave name, and adopted the X to represent the African name lost as a result of slavery. Malcolm X’s organizing skills and street savvy helped to expand the organization and vastly increase its visibility in the United States, while his oratorical gifts helped spread Elijah Muhammad’s message. In some respects this message was a form of neo-Garveyism: It endorsed black pride, self-help through economic enterprise, and the creation of a separate territory in the American South. However, the NOI’s unique, heretical interpretation of Islam—Elijah Muhammad was believed to be a prophet—set the organization apart from other black nationalist groups of the period. The NOI established mosques in cities across the country. Among their business activities were laundromats, restaurants, and a newspaper, Muhammad Speaks. The NOI also established separate schools for the children of its members.

The fact that the organization eschewed political engagement might have been its most striking feature. The late 1950s and 1960s was the period of civil rights
struggle, and the NOI did not participate in any of the major campaigns of the era. Indeed, in his *Autobiography* (1965) Malcolm X makes it clear that he was bothered by the common criticism of NOI—that it was all talk, and little action. After leaving the organization, he spent the final years of his life seeking to fashion a secular, and engaged version of black nationalism that was represented in his short-lived Organization for Afro-American Unity (OAAU). The OAAU called for black control of the various institutions that touched black life. Malcolm X, who was assassinated in 1965, might have had his greatest impact in death. Most nationalists of the Black Power era (post-1965) drew inspiration from the life and martyrdom of Malcolm X—especially his explicit rejection of integration as a goal of the black freedom struggle, and his questioning of nonviolence as a political strategy.

Among the groups operating during the 1960s and early 1970s that adopted and propounded an explicitly nationalist agenda were the post-1965 Student Nonviolent Coordinating Committee (SNCC) and Congress of Racial Equality (CORE), Mualana Ron Karenga’s US organization, the Revolutionary Action Movement (RAM), and the Black Panther Party for Self-Defense (BPP).

These organizations and activists were influenced by the anticolonial struggles of the 1950s, and especially the independence of a number of sub-Saharan African nations, starting with Ghana in 1957. Part of the inspiration came out of the fact that black activists in the United States and around the African Diaspora had long embraced Pan-Africanism—the idea that black people of the African Diaspora shared a common destiny. For nationalists of the period, the significance of these anticolonial struggles was also theoretical. First, activists understood anticolonial efforts as analogous to the struggle for civil and economic rights in the United States: Throughout the Diaspora, “African” liberation meant transforming, if not rejecting, Western social, political, and economic beliefs. Second, the nature of anticolonial struggle informed discussions of tactics within the United States. In some cases independence came peacefully. In other cases Africans gained political sovereignty through armed and bloody confrontation.

While proponents of black nationalism all pondered the same general questions during the 1960s, they arrived at different conclusions. Karenga, US, and “cultural” nationalists of the period believed that liberation was tied to the recovery of an “African” identity. Karenga therefore urged his followers to learn and speak Swahili, to dress in traditional African garb, and to live according to seven principles (the Kawaida) that distilled elements of an African cosmology. The Black Panther Party hoped to topple capitalism, and rejected the view that black equality could be achieved by changes in lifestyle that did not directly change political and economic realities. To help change those realities, they published a newspaper and established schools, health clinics, and free breakfast programs. US and the BPP were fierce rivals, and this rivalry (which in part was fueled by the FBI) proved deadly in 1969 when members of US shot and killed a member of the Los Angeles chapter of the BPP.

Both organizations, along with other black nationalist groups of the era, were active in what is known as the “Black Power” phase of the civil rights struggle. “Black Power,” first proclaimed as a slogan in 1966, had as many definitions as it did adherents. At base, its meaning was captured by another popular slogan of the time—“black faces in previously white places.” The basic idea—that blacks as a group should organize and pursue power collectively as other “ethnic” populations had done previously—was elaborated in Stokely Carmichael and Charles Hamilton’s *Black Power* (1967). Black Power demands for control of school curricula and city administrations coincided with the rioting (or urban rebellions) that marked the era—outbreaks that affected hundreds of cities across the United States. By the early 1970s, however, it was clear that Black Power represented conventional tendencies far more than radical ones. For a number of reasons, starting with the success of U.S. intelligence in undermining the strength of radical black nationalist organizations, Black Power soon looked more like “ethnic pluralism” than like a programmatic orientation that could transcend the terms of and limitations of urban politics in the United States (Allen 1970).

**The Post–Civil Rights Era**

In the post–civil rights context, the NOI has been the principal representative of black nationalism as a political movement. After the death of Elijah Muhammad in 1975, one of his sons, Warith Deen Muhammad, took control of the organization and adopted Sunni Islamic beliefs and practices. This meant, among other things, that the organization was no longer racially separatist, nor working toward political sovereignty. Louis Farrakhan subsequently led a group of defectors out of that organization and reestablished the NOI along traditional lines.

Farrakhan enjoyed considerable popularity among black Americans, especially during the early to mid-1990s. He drew large audiences to hear his lectures/sermons. Farrakhan organized the Million Man March in 1996, which drew upward of 750,000 black men to Washington, D.C. The Million Man March was intended to serve as a catalyst for the creation of a broad-based political movement that would tackle the problems that continued to plague black America—disproportionately high levels of unemployment, high rates of incarceration,
unequal access to capital, and so on. However, the fundamental theme of the march was “atonement,” and so— unlike the famous march on Washington of 1963, which demanded “Jobs and Freedom”—it demanded nothing but greater black male responsibility. It did not trigger a new wave of grassroots mobilization, and indeed might have had the opposite effect. By maintaining a view of political action that depends on “group consciousness” and eschews collaboration with movements that cross racial and class lines, such as organized labor, the NOI has not been able to transcend limitations that have hampered the organization from its inception.

Less overtly political, but also quite visible during the late 1980s and 1990s was the academic push for an “Afrocentric” paradigm. Afrocentric had once been synonymous with Pan-Africanist, but by the 1990s the term had developed a narrower connotation. Molefi Keté Asante of Temple University was the chief architect of this new usage. He insisted that to study “African” people—be they black Americans in Detroit, black West Indians in Barbados or Dominica, or the Wolof of Senegal—scholars must look to “classical” Africa, by which he meant ancient Egypt, or “Kemet.” Just as Ancient Greek thought provides the basis of Western philosophy, so too, he argued, did ancient Egypt serve as the basis of “African” philosophy. For Asante, this was more than an intellectual point. Rather, this counter-epistemology was a first step toward black empowerment. In this regard, Asante and proponents who shared his views extended the arguments of cultural nationalists of the 1960s—and of the NOI—who had insisted that black empowerment depended on an embrace of a lost cultural identity. Asante was not the first to emphasize an understanding of black or “African” history, nor to suggest that proper knowledge of identity could be emancipatory; however, Afrocentricity as Asante and other proponents spelled it out added ingredients of its time—especially the theoretical bent toward “post-structural” modes of understanding. In the end, though, his was only an attempt at a counter-epistemology. Despite Asante’s claim that Afrocentricity was a first step toward black empowerment, the conservative aspects of this ideology should be clear: This was fundamentally an intellectual, as opposed to a political, movement.

CONCLUSION
In a very broad sense, black nationalism and Black Power are not uniquely American phenomena. South Africa and more recently Brazil are other countries where activists have pushed for a consciousness about (black) identity as a way to catalyze and organize for social change. However, a proper understanding of black nationalism in any context requires special attention to the specificity of a given political and historical context. Simple analogies between movements that emphasize black or African identity invariably miss crucial differences. When scholars who revisit the Black Power era in the United States, or Black Consciousness in South Africa, focus on what activists did as well as what they said, the significance of local context becomes clear. Analogies to anticolonial struggle, or Pan-African solidarity, or black pride do not change the fact that black nationalists ultimately face the challenge of building social movements within national boundaries.

BLACK PANTHERS
The Black Panther Party (BPP) was conceived as the next stage in the evolution of the African American struggle, building off of a trajectory that is mistakenly divided into two discrete movements: civil rights and Black Power (Hill 2004; Tyson 1999). Fusing the political thought of Robert F. Williams on armed self-defense with the philosophy of Malcolm X on black self-determination, Max
Stanford developed a unique approach to activism that would become the Black Panther Party (BPP) (Marable 2007). The basic goal was to advance Black Power and national liberation throughout the United States in general but especially in the North by improving the political, economic, social, and psychological well-being of African Americans (Hilliard and Cole 1993; Holder 1990; Jones 1998). This was to be achieved through a diverse repertoire of activities, but it was the ideas of armed self-defense and guerrilla warfare (if deemed necessary) that garnered the most attention.

From the beginning the organization was divided by a fundamental split based on important tactical differences. On the East Coast the first BPP chapter was created in New York City by Stanford in 1965 (see Marable 2007). This organization advocated a clandestine approach and opted to remain underground until it could more effectively pursue its claims openly. On the West Coast the second BPP chapter was created by Huey P. Newton and Bobby Seale in Oakland, California, in 1966 (see Seale 1970). This chapter advocated a more public presence and attempted to garner as much attention as possible. Both wings of the party developed chapters throughout the United States (especially during a period of particularly rapid growth between 1967 and 1968). In late 1969 and 1970, in an effort to avoid negative publicity and the attention of authorities, the Panther name was changed to the National Committee to Combat Fascism in many locales.

Because it drew the primary focus of the media as well as of political leaders, activists, and academics, the West Coast faction has largely shaped our understanding of the BPP. This bias is perhaps inevitable, because the West Coast faction was involved in many of the most dramatic incidents and activities associated with the Panthers. These include the storming of the California State Assembly in Sacramento in 1967, numerous shoot-outs with the police throughout Oakland (especially those involving Newton, Eldridge Cleaver, and “Li’l” Bobby Hutton), the Free Huey movement, the Chicago 8 trial, the shooting of George Jackson in San Quentin Prison, and the failed kidnapping of a judge in a Marin County courtroom by Jackson’s brother Jonathan (see Holder 1990; Seale 1970; United States Congress 1971). In addition the West Coast Panthers developed numerous high-profile programs that were later imitated, such as the free breakfast program, the liberation school, sickle cell anemia tests, and the Black Panther Intercommunal News Service (see Abron 1993; Cleaver and Katsiaficas 2001). Also highly influential was the imagery associated with West Coast Panthers: Their military berets, leather gloves and hats, bright powder-blue shirts, and Afro hairstyles were as symbolically important to the Black Power movement as the phrase “Power to the People.” The impact of this imagery was immediate and resonated across the United States as well as throughout the world.

Although in some respects the BPP was part of a continuum of black struggle, in other respects it represented a major divergence from the traditional black nationalist program. For example, the BPP was hesitant about calling for a black “nation”—a major goal for black nationalists. Newton, the main theoretician for the Panthers, suggested that until “the oppressive state of America” was wiped out, there would be no freedom for blacks even with a separate state. The disagreement, then, was over timing, not over nationhood per se. The BPP members were also somewhat disdainful of those who believed that the path to African American salvation was the adoption of African culture or a return to the African continent—both major planks of the black nationalist program. Indeed the Panthers were quite American and Western in their objectives and in many of the means used to attain them. Finally, the BPP decided relatively early on that coalitions should be formed with white liberals, radicals, and any other groups that wished to bring about political-economic change—a stance that further distanced them from other black nationalists.

Divided tactically and organizationally from the rest of the Black Power movement, the BPP soon became the target of a highly repressive campaign. This effort extended from J. Edgar Hoover’s Federal Bureau of Investigation, which in 1968 identified the party as “the greatest threat to the internal security of the United States” (Cunningham 2004), to “red squad” and antisubversive units in local police departments throughout the country (Donner 1990). These organizations engaged in a wide variety of actions: setting up physical and electronic surveillance; sending false letters; planting informants and agents provocateur; conducting raids; making arrests for a multitude of offenses, from murder to running an intercom without a license; and even carrying out targeted assassination. The actions of both the state and the Panthers escalated to such a level of violence over several years that diverse citizens’ alliances began to form calling for an end to the conflict.

By 1973, due to the efforts of the U.S. government to eliminate it and the difficulties of managing a high-profile and contentious organization, the original BPP was effectively dismantled (Calloway 1977; Goldstein 1978; Hopkins 1978; Johnson 1998; Jones 1998). In its place there developed an organization with new leadership (most of the original governing committee was no longer involved), new tactics (confrontation was replaced by electoral and civil service efforts), and new members (largely female).

The Panthers were by no means finished at this time, however. Several of their earlier programs persisted up
until 1980 (Abron 1993). Ideologically and tactically, to both good and bad effect, the Panthers influenced the white Left (who considered them to be the “vanguard” of the revolution), other African American organizations (the New Black Panther Party), Latinos (the Young Lords), Native Americans (especially the American Indian Movement), diverse activists around the world (e.g., the Black Panther Parties in Australia and Israel as well as the Dalit Panthers in India), and even the social service programs of diverse state and local governments. Additionally, through popularization in film, television, music, poetry, and fiction, the BPP and its legacy continue to exert an influence on America and the rest of the world (Cleaver and Katsiaficas 2001; Kelley 2002). Indeed as one of the most visible and aggressive responses to the diverse problems confronting blacks in the United States, the Black Panthers are likely to remain inspirational to those resisting racism, the U.S. government, or capitalism for some time to come.

**BIBLIOGRAPHY**

Carmichael, 1941–1998) defined Black Power as "the ability of black people to politically get together and organize themselves so that they can speak from a position of strength rather than a position of weakness" (quoted in Ladner 1967, p. 8). It is apparent though, that while the Black Power movement was a continuation of the struggle waged by the civil rights movement, it was distinct in many ways.

Black Power organizations such as the Black Panther Party, US, the Republic of New Africa, the League of Revolutionary Black Workers, the Revolutionary Action Movement, and others saw themselves as the heirs to Malcolm X (1925–1965). Malcolm had argued that the nonviolent tactics of Dr. Martin Luther King Jr. (1929–1968) were not a viable option for black people. Malcolm viewed integration as a surrender to white supremacy, for its aims of total assimilation into white society implied that African Americans had little that was worth preserving.

Malcolm's candid and fiery rhetoric appealed to many urban blacks, and his autobiography was devoured by Black Power advocates. Nat Turner (1800–1831), Che Guevara (1928–1967), Frantz Fanon (1925–1961), Amílcar Cabral (1924–1973), Kwame Nkrumah (1909–1972), Patrice Lumumba (1925–1961), Sékou Touré (1922–1984), and Toussaint Louverture (1743–1803) were also held in high regard. Black Power advocates were inspired by the struggle for African independence.

For many in the Black Power movement, Fanon's *The Wretched of the Earth* (1961) was considered a blueprint for revolution in America. *The Wretched of the Earth* distilled the lessons of the Algerian war for anticolonial movements everywhere. In terms of organization building, Garvey's UNIA served as a model for many Black Power advocates.

The 1965 assassination of Malcolm X coupled with the urban uprisings of 1964 and 1965 ignited the Black Power movement. Some young black activists committed themselves to continuing the unfinished work of Malcolm X's Organization of Afro-American Unity by forming their own organizations. During the summer of 1965, the primarily black Watts district in Los Angeles reached its boiling point and erupted in violence in response to the mistreatment of a black motorist by members of the California Highway Patrol. This uprising was arguably the most catastrophic of its era; it signaled to America that some blacks were willing to lash out against the establishment in a violent way when consistently denied the most basic of human rights. Ironically, this rebellion occurred just a few days after the passing of the Voting Rights Act of 1965. Consequently, for many blacks it was clear that oppression was too deeply entrenched in America's institutions to be overcome by civil rights legislation that addressed the symptoms and symbols of black inequality rather than the root causes.

By 1968 the Black Power movement was in full gear. Thousands of blacks all over the country took to the streets in response to the killing of Dr. King. Months later, black athletes staged protests at the Olympic Games in Mexico City as a way of bringing attention to the plight of African Americans in the United States.

The Black Power movement was dispersed throughout the United States. The civil rights movement, on the other hand, was to a large extent a southern-based movement. Unlike the civil rights movement, whites were prohibited from joining any of the Black Power organizations. With the exception of the Black Panther Party, Black Power organizations did not form alliances with white groups. Black Powerites sought to be free of any white influence or interference.

While all of the Black Power organizations believed in black control of their communities, they were not monolithic in their approach to that end. The civil rights movement sought to dismantle Jim Crow in public accommodations and to exercise the right of black Americans to vote. For many Black Powerites, integration was a nonissue and nonviolence was out of the question. The political philosophy of the organizations that comprised the Black Power movement ran the gamut. Some were black nationalist, others were cultural nationalist, while still others considered themselves Marxist-Leninist.

The Black Power movement was preoccupied with increasing black people's level of consciousness. Black people began calling themselves black instead of negro. Congressman Adam Clayton Powell (1908–1972) of New York spoke of Black Power at a rally in 1965 in Chicago and elaborated on it in his Howard University commencement speech the following year. He exclaimed that Black Power was "a working philosophy for a new breed of cats … who categorically refuse to compromise or negotiate any longer for their rights … who reject the old-line established white financed, white controlled, white washed Negro leadership" (quoted in Muse 1970, p. 242).

The Black Power movement not only represented a change in tactical strategy, but also a change in mind-set. For instance, the black music industry, with its roots in gospel and rhythm and blues became nationalist in an extraordinary way. Songs like James Brown's "Say It Loud, I'm Black and I'm Proud" (1968), the Temptations' "Message to a Black Man," (1969) and the Impressions' "We're a Winner" (1967) established a distinctive sound that became the preferred expression for a generation of politically conscious young black Americans. Some blacks chose to don African garb and adopt African names. Some chose to wear their hair in ways that were more distinctively nonwhite. In the fall of 1966, Howard University
students elected as homecoming queen a woman who ran on a Black Power platform and wore the emerging Afro hairstyle. “Black Is Beautiful” became the mantra among Black Powerites.

Young black activists from Cornell University in Ithaca, New York, to the University of California at Berkeley established black student unions and demanded black studies programs, more black faculty, and proactive recruitment and admissions policies. Black Power advocates claimed that most African Americans knew little about their history. Carter G. Woodson (1875–1950) had made the same point years earlier: “The Negro knows practically nothing of his history and his ‘friends’ are not permitting him to learn it…. And if a race has no history, if it has no worth-while tradition, it becomes a negligible factor in the thought of the world, and it stands in danger of extermination” (Wiggins 1987, p. 45; Young 1982, p. 100).

Black Power advocates felt little need to prove to whites that they were deserving of the same rights. From their standpoint, to whom were whites to be equal? They believed that their time would be better spent educating the community, building institutions, and meeting the daily needs of the people by providing protection, food, shelter, and clothing.

The Black Power movement did not grow out of a vacuum; it was firmly rooted in the rich tradition of black protest. Like the slave rebellions and the Garvey movement, it was extensively organized. Its use of the written word, art, and culture to heighten the consciousness of the black community also linked the movement to the Harlem Renaissance (or the New Negro Renaissance), which relied heavily on these black expressive endeavors.

The Black Power movement also heightened the consciousness of other oppressed peoples throughout the world and greatly influenced the direction of their movements. The Black Power movement had a profound impact, for example, on the struggle for equality in the Caribbean, where freedom fighters started the Afro-Caribbean movement, activists in Barbados formed the People's Progressive Movement, and grassroots organizers in Bermuda launched the Black Beret group (Jeffries 2006).

By the mid-1970s, the Black Power movement was for all intents and purposes over. Government repression, which included assassinations of Black Panthers Mark Clark and Fred Hampton in Chicago, and Carl Hampton of Houston, raids, arrests, and harassment of many of the movement's members, gets much of the credit for the decline of the Black Power movement. In addition to repression, by 1973 African American activists had begun to concentrate their efforts on getting blacks and progressive whites elected to public office. Some saw the electoral process as a significantly less dangerous undertaking. Intragroup squabbles and government programs such as welfare (which underwent a loosening of eligibility requirements) also worked to dampen militant activism. While a few Black Power organizations remained active well into the mid-1970s, by the time of the election of President Jimmy Carter in November 1976, the Black Power movement was dead.

**BLACK SEPTEMBER**

The Black September Organization (BSO) was a Palestinian terrorist group most active in the early 1970s. The BSO named itself after the particularly bloody month in 1970 when King Hussein of Jordan declared military rule, expelling and killing thousands of Palestinian *fedayeen* (self-sacrificers). These *fedayeen* threatened to undermine Hussein's power in working with a “state within a state,” the Palestine Liberation Organization (PLO), established to mobilize the Palestinian population against Israel. Black September most likely began as the...
Revenging Palestinians, a group dedicated to avenging the death of Abu Ali Iyad, the last charismatic leader of the fedayeen, whose torture and murder was intended as a symbol of defeat for the Palestinian guerrillas. After regrouping in Lebanon, where they were given control of fifteen refugee camps by the government, the Revolutionary Council of al-Fatah (the PLO’s military force) met in Damascus, Syria, and debated whether it should continue using the tactics of Iyad’s followers. The council, it is suspected, agreed to remain affiliated with the group, which later renamed itself Black September, and agreed to operate as a clandestine arm of al-Fatah.

Black September carried out its first act of violence on November 28, 1971, with the assassination of Jordanian Prime Minister Wasif al-Tali. Al-Tali, believed to have personally killed Abu Ali Iyad, was attending the Arab League summit in Cairo, Egypt, when four gunmen shot him outside the Sheraton Hotel. The BSO also attempted to assassinate King Hussein and Zaid al-Rifai, Jordan’s ambassador to London and former chief of the Jordanian royal court, in December 1971. These acts of revenge foreshadowed several bold attempts that the BSO would make to alter the political landscape of the Middle East and advance the cause of the Palestinian people.

The BSO is probably best known for taking members of the Israeli team as hostages on September 5 of the 1972 Munich Olympics. In return for the hostages, the BSO demanded the release of roughly 220 prisoners (mostly Palestinian) from West German and Israeli jails. After attempts to negotiate failed, the BSO members demanded to be transported by helicopters, with the Israelis in tow, to the nearby military base of Fürstenfeldbruck, where they hoped to board a jetliner that would allow them to escape to an Arab country. Shooting broke out between German officials and the BSO at Fürstenfeldbruck as West Germany made its last attempt to prevent the hostages from being taken out of the country. By the end of the bloody ordeal early September 6, all eleven Israeli hostages were dead (two at the Olympic village, the other nine at Fürstenfeldbruck). Also killed were five members of the BSO and one German police officer, shot at the airbase.

In response to the massacre at Munich, Israel declared war on terrorist activity and targeted Black September and al-Fatah equally. Some of Israel’s immediate retaliatory acts included killing hundreds of people, most of whom are believed to have been unaffiliated with the terrorist group, during raids of Palestinian refugee camps in Lebanon and Syria. These attacks added to already existing tensions between Israel and its neighboring Arab nations, and they would ultimately lead to further military conflict. In the fall of 1973 the PLO dissolved Black September. A year later Yassir Arafat, the PLO’s leader, ordered his followers to withdraw from acts of violence outside Israel, the West Bank, and the Gaza Strip.

BLACK SOCIOLOGISTS

Because race and social inequality have been central points of concern in sociology, it is not surprising that the discipline has a rich and deep history of contributions from African American sociologists. Indeed, prior to the emergence of sociology as a formal field of inquiry, African Americans were constructing and applying what would later become bedrock tools for sociological research. One such individual was Ida B. Wells (1862–1931), a journalist and social activist who documented and advocated against the lynching of African Americans in the postbellum South. In order to make her case she conducted what may have been the first formal field studies of lynchings. She accumulated statistics on the frequencies of lynchings and assessed that data in terms of the rationales given (at least in public records) for these events and the socioeconomic conditions of the communities where such events occurred. Ultimately, she discovered that occurrences of lynchings were not so much due to perceived or actual incidents of sexual interaction between African American men and white American women, but to vast increases in the business activity and economic success of African Americans residing in or near communities where lynchings occurred. Having conducted her investigations in the late 1800s, Wells stands as a pioneer figure in the statistical analysis of causal relationships.

A few years after Wells’s foray into social analysis, W. E. B. Du Bois (1868–1963) initiated a more formal sociological agenda for research on black Americans. In publishing The Philadelphia Negro (1899), Du Bois introduced a multimethod approach (including ethnography, demographic and document analysis, and historical inquiry) for the purpose of producing a comprehensive study of an urban-based, African American residential community. Du Bois also published The Souls of Black Folk (1903), which helped establish, among other objectives, a tradition of social theoretical considerations or the social significance of race, racial identity, and race relations.
Anna Julia Cooper (1858?–1964) was a much-less recognized, but still highly significant, contributor to a black sociological tradition. She was the first African American woman to obtain a PhD in sociology (receiving one in 1925 from the Sorbonne in France, decades after she completed the majority of her writings). In her work, mostly published in the late nineteenth century, she argued for a feminist perspective on the African American condition by exploring what she believed to be the rightful place of women in both civic affairs and on the home front.

In the decades following the contribution of these figures, and after the founding of the first department of sociology in the United States (at the University of Chicago in 1895), other African Americans emerged in the discipline to advance research on, and interpretation of, the African American social condition. In the first half of the twentieth century, the University of Chicago’s Department of Sociology produced: E. Franklin Frazier (1894–1962), who pursued a social-organizational approach to studying the African American family and African American adjustment to the urban sphere as a result of the southern to northern migration; Charles S. Johnson (1893–1956), who studied the social-psychological impact of racism and discrimination on African Americans; St. Clair Drake (1911–1990), perhaps more formally known as an anthropologist, but who, with sociology student Horace Cayton (1903–1970), explored the cultural and social-interactive dimensions of African American adjustment to the urban sphere; and Oliver C. Cox (1901–1974), who introduced a Marxist-informed paradigm for exploring what he regarded to be the caste-like arrangement of racial groups in the United States, which he also situated in a larger world-systems framework for understanding how capitalism encouraged racial subordination and conflict. Other African American sociologists who published between 1910 and 1950 also contributed to a canon of African American sociology that largely focused on the social problems and prospects associated with African American migration to metropolitan regions (e.g., Ira de Augustine Reid [1901–1968] and George Edmund Haynes [1880–1960]).

By the post–World War II era, many African American sociologists began expressing frustration with the dominant sociological paradigm that emphasized assimilation and accommodation to a rapidly maturing Western capitalist society. Their frustrations were not only based on the historical exclusion of African American sociologists from the canon of the discipline, but also the perceived inadequacy of assimilation perspectives for interpreting the social condition and possibilities of the African American community. This frustration, coupled with the motivation to pursue new frames of thinking, were captured in The Death of White Sociology (1973) edited by Joyce Ladner. In this and other works produced between 1960 and the early 1970s, many African American sociologists began calling for studies of the positive aspects of African American identity and the virtues of varied patterns of family formation, peer associations, and other social processes and organizational dynamics that reflected strong differences between black Americans and others in the American landscape.

While some of the claims and arguments made during this period were challenged in later years for being more polemical than scholarly, the efforts of many African American sociologists during that time did result in the creation of the Association of Black Sociologists in 1972 (which, itself, had origins in the Black Sociology Caucus, which was created following the 1969 American Sociological Association meetings in San Francisco). The creation of the association resulted in there being a more pervasive sense that African American sociologists had achieved a visible and durable status in the mainstream areas of the discipline. Since the 1960s, some African American sociologists assumed central positions in the discipline as they helped introduce or define areas of inquiry that constitute much of the contemporary agenda of the discipline. For instance, urban poverty research became a major subfield in sociology as a result of the publications of William Julius Wilson, who emphasized the importance of taking a structural perspective on the social location and concentration of the urban poor as a foundation for better understanding certain behavioral and cultural dynamics that became manifest for this constituency. Furthermore, Patricia Hill Collins has advanced African American feminist theory in sociology through her publications. Moreover, Lawrence Bobo has advanced survey research on racial attitudes in the post–civil rights era in the United States.

Professors Wilson, Collins, and Bobo represent some of the most visible African American sociologists in American sociology. One reason for their visibility is that rather than trying to advance a distinct and autonomous field of African American sociology, they have striven to incorporate the ideas, arguments, and methods of sociology more generally into specific considerations of African Americans. The changing American racial landscape, largely a by-product of the civil rights era, created the space for these sociologists to function more effectively as mainstream scholars. Despite their rich and varied contributions, the African American sociologists of previous periods were often relegated to African American higher educational institutions in a segregated southern region of the country, where their work was not incorporated into the mainstream canon of the discipline. Accordingly, the methodological, theoretical, and empirical contributions of these early figures often do not get registered (or do not get registered as fully as they should) as significant
moments in the progression of American sociological thought.

The success of figures such as William Julius Wilson and Elijah Anderson in achieving mainstream status has not come without certain criticism. Contemporarily, those and other higher-profile black sociologists have been read as traditionally liberal rather than critical analysts of American social inequality. Consequently, it has been argued that their achieving of mainstream status came about through their promoting or implying more passive and sanitized assessments of mainstream American society rather than the progressive, critically centered, and Marxist-infused perspectives of early figures such as Du Bois and Cox, who indicted American and global capitalism and its cultural manifestations more directly and fully as causal factors for the enduring social predicament of African Americans.

BLACK TOWNS

African Americans have a long history of forming separate settlements and towns in what is today the United States. More than eighty black towns and settlements were established in the United States in the nineteenth and twentieth centuries. Prior to the Civil War, most black settlements were informally organized. Brooklyn, Illinois, founded in 1830 by runaway slaves and Quakers, was an exception to this general rule. Most black towns were formed after the Civil War and could be found all over the United States from Eatonville, Florida, to Allensworth, California. However, most of these towns were established in the Midwest and Southwest between the end of Reconstruction and World War I. During this period, often referred to as the “nadir” of African American history, many black southerners lost hope that their rights and freedoms would ever be protected in white-dominated communities. Some African Americans contemplated emigrating from the United States to escape the violence, racism, and discrimination they were forced to endure, but others attempted to form separate enclaves within the United States. Although these towns were usually very small, their citizens owned property, governed themselves, educated their children, and ran their own farms and businesses. Like other small towns, over the years black towns often struggled to remain economically viable. Most black towns lasted only a few decades, but a few continue to survive today.

Two of the oldest and longest surviving black towns in the South were Eatonville, Florida, and Mound Bayou, Mississippi. Founded in 1886 and incorporated in 1887, Eatonville was the beloved childhood home of Zora Neale Hurston. Mound Bayou was founded in 1887 by Isaiah T. Montgomery but has its roots in an antebellum slave community known as Davis Bend. Booker T. Washington was a strong supporter of Mound Bayou. Although their development and growth were curtailed by racism and limited economic opportunities, both Eatonville and Mound Bayou continue to function today.

The history of Rosewood, another Florida black town, demonstrates the extreme effects of racism that black towns could be subject to. In January 1923, a white woman from a neighboring community accused a black man of attacking her. Over a period of several days, white vigilantes sought out residents of Rosewood whom they believed aided the alleged attacker. Their attacks escalated from lynching individuals to an all-out assault on the town and its residents. As the town was torched, residents escaped to nearby swamps where they hid for days. Those who did not escape to the swamps, including the elderly and infirm, were murdered. Seventy years later the state of Florida granted reparations to the surviving victims of the riot.

One of the best known black towns in the west, Nicodemus was founded in Kansas in 1877. It was a popular destination for Exodusters, southern blacks led into Kansas by Benjamin “Pap” Singleton. Singleton, a former slave from Tennessee, helped lead a movement of 10,000 to 20,000 blacks from Louisiana and other southern states into Kansas. Although most of the migrants settled in cities, others continued on to live in Nicodemus or one of the other black colonies founded by Singleton and other African Americans in western Kansas. In 1879, at the height of the Kansas migration movement, Nicodemus
had a population of about 700 people. Early settlers endured difficult conditions, including bad crops, but they held on to the belief that the railroad would come through their town and make it an economically viable place. Unfortunately, Nicodemus could not survive the decision of the Union Pacific Railroad to build away from the town, and it began to decline by 1887.

Oklahoma was home to more black towns than any other state in the nation. Some of these towns predate 1889, the year the Oklahoma Territory officially opened to non-Indian settlement. Others were founded in Indian Territory before or after Oklahoma statehood in 1907. In the early days of black settlement in Oklahoma, some blacks, led by Edward P. McCabe, lobbied to make the future state all black. McCabe was a native New Yorker, but he had moved to Kansas in 1878, been part of Nicodemus, and then was elected Kansas state auditor. Although his efforts to be appointed territorial governor of Oklahoma failed, McCabe moved to Oklahoma Territory in 1890 and founded the town of Langston, which became home to Langston University in 1897. The choice by founders to give these settlements such names as Langston, Vernon, and Bookertee, in honor of important black statesmen such as John Mercer Langston, William T. Vernon, and Booker T. Washington, reflected the inspirations and aspirations of their inhabitants.

The largest and most famous of Oklahoma’s black towns was Boley, founded in 1903 by an interracial group. Unlike many black towns, Boley had a railroad, which brought in new settlers by the carload and shipped their cotton to market. Boley and several other black towns had newspapers that were sold all over the South and used to encourage black Southerners to emigrate to them. By 1910, Boley had a population of over 1,000 with as many as 5,000 black farmers living around the town.

When Oklahoma became a state in 1907, the hopes of black townspeople came to a halt. The first law passed by the new state congress segregated public schools and public conveyances such as trains and streetcars. Then in 1910, the state passed a law that disenfranchised blacks. These laws were accompanied by an increase in violence against blacks. There were lynchings, and some towns and counties tried to run all African Americans out of their borders. In spite of these setbacks, Boley’s population remained strong until the late 1920s and 1930s, when the Great Depression forced many of its residents to head to cities in the North and West.

**BLACKFACE**

Blackface, which dates back to as early as the Middle Ages, is the theater performance practice of wearing soot, cosmetics, paint, or burnt cork to blacken the face. In medieval and Renaissance English theater, blacking up was prevalent in religious cycles and morality plays, where it was used to represent evil, badness, or damnation. Evil characters were portrayed with the color black in order to suggest that they were the antithesis of white, which stood for goodness, purity, or salvation. Blackface was also commonly used as a signifier of negative attributes in other realms of English life. As European global exploration progressed, blackface on the stage began to be used to represent newly encountered peoples of the world.

The sixteenth century witnessed a rise in the variety of blackface characters as a result of the popularity of William Shakespeare’s plays. In one of the most famous of Shakespeare’s plays, *Othello*, the main character is a Moor, who was often portrayed by a white man in blackface. Shakespeare’s plays brought a change in the role of blackface characters from merely symbolizing evil, to signifying the social expectations and ideals of black people. At the same time, the negative attributes of blackface were reflected in the development of the African as the “exotic other” in Western society.

**BLACKFACE IN NORTH AMERICA**

In the New World, the institution of slavery contributed to the continuance and evolution of blackface characters on the theater stage. In the eighteenth-century United States, white traveling actors known as Ethiopian Delineators, who used burnt cork to blacken their faces, sang slave songs between the acts of plays. These performances, which were given in England as well, slowly began to grow in popularity and developed into lengthy spectacles known as minstrel (or minstrel shows).

The first mainstream minstrel character, Jim Crow, was introduced in the 1830s by Thomas Dartmouth Rice on a Northern stage. The minstrel show consisted of satirical portrayals of black Southern plantation slaves, presented by white male performers with blackened faces, lips colored to suggest exaggerated size, wooly wigs, and ragged clothing. Minstrel shows were one of the most
popular forms of entertainment in the United States from the 1840s to the 1880s, and did much to disseminate and perpetuate negative stereotypes of blacks in America. After the Civil War, African Americans themselves began to blacken up their faces and perform on the minstrel stage. Blackface was also adapted by European immigrants: Irishmen, Italians, and Jews began to blacken their face in minstrel shows during the early twentieth century and developed some of the most popular blackface characters. Blackface offered to these European immigrants a way to become accepted as American whites through their embrace of the racist ideology dominant in the United States. Immigrants erased the negative stereotypes associated with their ethnic group by using blackface to highlight their “normalcy” in comparison to blacks. For blacks in America, however, minstrel shows functioned as venues for their public humiliation and degradation.

The emergence of film as the new dominant entertainment medium led to the transitioning of blackface characters from theater stage to screen. In the 1920s and 1930s, films continued the tradition of the blackface minstrel show. One of the most famous blackface performers was the Jewish actor Al Jolson. The negative stereotypes of blacks that blackface actors created and perpetuated were manifested beyond stage and film in literature, advertisements, comic strips and comic books, postcards, cookie jars, lawn accessories, and other consumer products. The popularity of blackface in American culture influenced its extension to the international community.

INTERNATIONAL BLACKFACE

Traveling theater troupes introduced the blackface satirical performances of the American minstrel to several countries. Ironically, blackface shows that were initiated in England returned within the American minstrel in the mid-nineteenth century. British audiences consumed the blackface performances from the United States and created their own national variant through blackface characters such as the Golliwog.

U.S. influence on the internationalization of blackface is demonstrated by the development of the Cape Town Coon Festival in Cape Town, South Africa. In the late nineteenth century, Orpheus M. McAdoo and the Virginia Jubilee Singers traveled to South Africa, where they remained for almost five years. These traveling troupes introduced the American blackface minstrel performance style and greatly influenced the emergence of the blackened Coon disguise used in a grand festival held in the city center of Cape Town, the origins of which can be traced back to the late 1880s. This festival, the name of which was changed to the Cape Town Minstrel Carnival in 2003, continues to present blackface displays and is one of the area’s most famous tourist attractions.

Traveling American minstrel troupes also influenced the development of Cuba’s teatro bufó, a form of comedic blackface performance featured in musical and theatrical entertainment. Blackface performances first appeared in Cuba in the mid-nineteenth century, as part of a range of satirical representations of the African found throughout Cuban literature, theater, and music.

The broad influence exerted by the American blackface minstrel also contributed to the development of blackface characters in Mexico. Memín Pinguín, a fictional and stereotypical Mexican blackface character, first appeared in a comic book in the 1940s. He was a popular, if controversial, figure, and the comics he was featured in continued to be published until the 1970s. In June 2005, the Mexican Postal Service issued character stamps with images of Memín, sparking international controversy.

The above-mentioned countries are only a few of the many that incorporated blackface: It was also performed in Jamaica, Nigeria, India, China, Ukraine, Indonesia, Australia, the Netherlands, and Spain, among numerous other countries. Blackface, which still continues to be performed throughout the world, has done much to continue and disseminate negative stereotypes of African Americans throughout the globe.

Blackness

Blackness is first a descriptive category that refers to people of African descent and the degree to which they look like the African stereotype before and after their biological mixture with other groups in the Atlantic world. The mixtures referred to here began with Africa’s contact with Europe and continued with the slave trade, the creation of African communities in the New World, and the rise of colonialism. The varying shades of blackness created competing and contradictory definitions of whiteness and blackness. The phenotypical attributes of individuals—hair texture, dark skin, blunt features, and body type—became the physical markers of blackness, but as these markers were compromised by racial mixture, it became necessary to certify whiteness.

Racial mixture required new terms to ensure the “purity” of whiteness. For example, in Europe, Latin America, and Africa, terms such as preto (black), mulatto (half-white, or brown), mestizo (Indian and white), and many more were commonplace by the eighteenth century. Another means to certify whiteness was to define blackness legally. In the United States, for example, the “one drop rule” rendered anyone with even one known drop of black blood as legally, fractionally black. Racial mixture was codified in law. Mulatto (one-half black), quadroon (one-quarter black), and octoroon (one-eighth black) were social and legal categories to determine who was not fully white. As more and more individuals had features that suggested white ancestry—straight or wavy hair, thin features, or brown to very light skin—blackness based on physical type alone was unstable. In the United States blackness had to include mixtures. In Latin America and elsewhere, mixture was often a means of distancing oneself from blackness but rarely allowing one to be white. In the United States, the only option was to pretend to be white or present oneself as white, provided the physical markers and cultural bearing allowed the deception. This practice was known as “passing” and hundreds, perhaps thousands, managed to pull off the deception.

In South Africa, in contrast, “black” referred to all those of African appearance, and “colored” signaled those of mixed background, with whites as the pure, uncontaminated group. East Indians in South Africa were also a separate group, but in England, East Indians embraced their own version of blackness. Their physical darkness had meaning in this context. Blackness and whiteness are therefore linked in these societies to the extent that who is black can only be ascertained by determining who is white. But blackness also exists in societies with no significant white population. In Guyana and Trinidad, for instance, blackness exists in a population that is dominated by other dark-skinned people; East Indians.

Physical features other than color become salient in these societies, and culture takes on profound meaning.

Black Consciousness

Blackness, secondly, is a conscious mental attitude expressed in political practice, social organizations, and commitment to the group. It is embraced by those who by law or custom experience racial discrimination and identify themselves as a group in the struggle toward the realization of their aspirations. Black consciousness is also concerned with the consequences of defining oneself as black. It forms the basis for a transnational politics and subjectivity that creates relationships between Africans in Africa and the African diaspora.

In the eighteenth and nineteenth centuries black consciousness was expressed in slave revolts and runaway slave communities known as “maroons.” Free blacks organized against slavery as well as struggled for their rightful place in society. After slavery ended, black consciousness took many forms that were grounded in an affirmative black identity. In the postbellum U.S. South, black towns emerged to form self-sustaining communities that remained relatively free from the harsher elements of Jim Crow society. But in this segregated world, the act of choosing separation and becoming economically independent invited the very violence that blacks sought to avoid. By the 1920s not only was lynching commonplace, but inhabitants in all-black towns and the “black backside” of white towns were targets of white terror. The all-black section of Tulsa, Oklahoma, was leveled in 1921 by angry whites who destroyed black businesses, churches, banks, and all signs of black independence. In the same decade, the black inhabitants in Rosewood and Ocoee, Florida, were massacred, their homes and businesses destroyed. Black consciousness that resulted in economic and political parity was not to be tolerated. This racial violence and the discrimination that it supported were key elements in forging a black consciousness and a sense of group affiliation and pride that led to an activism characterized by black self-help and political formations that spoke to needs of the black underclass. Organizations such as the National Association for the Advancement of Colored People (NAACP), the Nation of Islam, the United Negro Improvement Association, the African Blood Brotherhood, the black women’s club movement, black unions, and many more fought for black rights and achievement in the early part of the century.

This assertive black mentality found expression in the modern black freedom struggle and the black power movements of the 1960s and 1970s. In the United States, with boycotts of segregated institutions, freedom marches, and political activism, blacks achieved the removal of the most egregious forms of segregation, if not complete eco-
nomic and social parity. These movements were possible in large measure because of the deep sense of historical and cultural separateness blacks feel as a people. Pride and a commitment to the freedom struggle underpinned a race-based black nationalism that had been evident in the nineteenth century and flowered dramatically in the twentieth century.

Similarly, in Brazil after slavery ended in 1888, former slaves and free blacks struggled to challenge the racial discrimination that relegated them to second-class citizens. Black Brazilians (preto) found themselves locked at the bottom of a hierarchy defined by gradations of color with whites at the top. Morenos, mulattos, and mestizos (mixed race), in contrast, fared better socially and economically. As in all of Latin America, whites in Brazil held political and economic power while colored folk jockeyed for positions relative to whites, often using their distance from blackness as a measure of social and political success. Yet, by the twentieth century, blacks in Brazil had formed organizations that specifically addressed racial discrimination and their position as blacks. In the 1930s they formed the Frente Negra Brasileira (Black Brazilian Front), an organization concerned with racial uplift, integration, and Afro-Brazilian mobility. In the 1970s and 1980s a flurry of organizations appeared in Brazil focusing on blackness and black issues, the most important being the Movimento Negro Unificado (United Black Movement).

In Spanish-speaking America, too, black groups pushed for inclusion through activism and protest. In Cuba, for example, during slavery the cabildos da naciones (council of nations) retained ethnic identities and created new ones based on memories from an African past. The survival of African belief systems and cultural forms facilitated an African ethnic consciousness well into the twentieth century. But alongside these African cultural forms, a more generalized black consciousness also emerged that unified free and slave populations. From these formations, leaders with a distinct black consciousness emerged in the late nineteenth century to challenge slavery and efforts to subject black people to white racist domination. One organization that grew from these slave nations and the revolutions in 1868 and 1898 against slavery and Spain was the Partido Independiente de Color, the first black political party in the Americas (1908). Its purpose was to work for inclusion within the Cuban state and a national identity that embraced black people as Cuban. Both Africans (i.e., dark-skinned persons) and mulattos were members of this organization, and they affirmed a black political identity as Afro-Cuban. The efforts to create a Cuban identity that was both black and Cuban resulted in a violent backlash in the race war of 1912, when members of the Partido were massacred by white Cubans. In the aftermath of this massacre, blacks did not abandon their black consciousness, but were forced to articulate that consciousness culturally and intellectually rather than in political organization.

Black voices were more audible in the years after the Cuban Revolution in 1959. Although the economic and social situations improved, racism has not been eliminated and, in some respects, has increased particularly in moments of extreme economic distress. The strength of Afro-Cuban culture and the long tradition of black consciousness in Cuba has created a black Cuban identity that is both black and Cuban.

In other parts of Spanish America, attempts to forge a black identity have met considerable resistance, historically. In Puerto Rico and the Dominican Republic, for example, blackness was not only denied, but also challenged with the powerful ideology of mestizaje (the racial and cultural mixing of Amerindians and Europeans), which excludes both blacks and indigenous people. Yet, black groups in each society have maintained their autonomy and challenge the official interpretation of their heritage as Spanish and not African.

The migration of so many Puerto Ricans to the United States has aided the continuation of a black consciousness among both dark-skinned and mixed-race members that often brings them into conflict with white Puerto Ricans. Class differences as well as the overt racism in the United States and Puerto Rico are also important factors in the development of black consciousness among Puerto Ricans. Mestizaje has had an even more powerful impact upon Dominicans, and their location in the United States has exposed the contradictions inherent in their physical blackness and their determination to claim a mestizo consciousness despite the racism that they experience in the United States.

In the English-speaking Caribbean, a consciousness based on color emerged during and after slavery. A white colonial class and a colored elite dominated a peasant and working-class black majority. In Jamaica, efforts to challenge this domination took shape in many movements such as Rastafarianism, the Garvey movement, and the black power movements of the 1970s. In Trinidad as well, black consciousness found expression in organizations and challenges to colonial authority. A black power movement emerged there in the 1970s, as it did in several other islands. These movements testify not only to black consciousness in the islands, but also to the links between African societies in the diaspora.

BLACK CULTURAL TRADITION

Blackness, thirdly, is a cultural signature that transcends physical markers, and often transcends, under certain historical conditions, national identifications. It is expressed in language, mannerisms, dress, hairstyles, cultural forms,
social organization, and religious practices. Languages formed from the amalgamation of African, European, and Indian languages pepper the west coast of the Atlantic. Dialects and tonal cadences of blackness in English, French, Spanish, Portuguese, and other European languages are spoken in African communities, and often are rejected as part of the larger culture in which the group resides—that is white or European culture.

Black intellectual traditions in all of these societies emphasize the heroic efforts of slave rebels and military leaders such as Haiti’s Toussaint Louverture (c. 1739–1803) and Jean-Jacques Dessalines (1758–1806); freedom fighters such as Jamaica’s Sam Sharpe (1801–1832) and Marcus Garvey (1887–1940); civil rights giants such as the United States’ Martin Luther King Jr. (1929–1968); and revolutionary leaders such as Guyana’s Walter Rodney (1942–1980), Puerto Rico’s Jesús Colón (1901–1974), Mozambique’s Amílcar Cabral (1924–1973), and Ghana’s Kwame Nkrumah (1909–1972). Radical thinkers such as the Americans W. E. B. Du Bois (1868–1963) and Richard Wright (1908–1960), the Barbadian Richard B. Moore (1893–1978), the Trinidadian C. L. R. James (1901–1989), the Puerto Rican Arturo Schomburg (1874–1938), the Martinican Frantz Fanon (1925–1961), and the American Malcolm X (1925–1965), among others, established the norms of black thought.

This approach to black consciousness often denies the importance of gender and sexual difference. Feminists and homosexual members of the group also embrace blackness, but in so doing, critique the masculine bias often inherent in notions of race pride, authenticity, and stigmatization. Black intellectual traditions have tended to construct the black subject as masculine and North American, thereby erasing the feminist and diasporic perspectives on black consciousness. These traditions have been equally resistant to homosexual perspectives. The perspectives of women and homosexuals in black communities render black consciousness as a contested terrain of gender and sexual politics, where the very definition of consciousness is at stake.

BLAIR, TONY

1953–

Born on May 6, 1953, in Edinburgh, Scotland, Tony Blair was elected Member of Parliament (MP) for Sedgefield in 1983. He became leader of the Labour Party in 1994, and prime minister of the United Kingdom (UK) in 1997. He played a key role in resetting Labour Party policy in the early 1990s, a resetting designed to address three things: Labour’s inability to win general elections; the impact of Prime Minister Margaret Thatcher’s neoliberal policies on UK politics and society; and the need to reposition the United Kingdom in the new global age. Blair responded to four election defeats in a row by reaching out to median floating voters, and by making real and symbolic breaks with Labour’s previous policy stance. He responded to Margaret Thatcher’s powerful legacy by linking her passion for markets to Labour’s traditional commitment to social justice. He actively welcomed globalization as a trigger to UK economic competitiveness and as an arena in which a Labour government could play a more active and ethical role.

Blair led the Labour Party to three election victories in a row, the first two (1997, 2001) with huge majorities (179 and 167 seats in the House of Commons, respectively). The 1997 victory came after a relabeling of the Labour Party as New Labour, and the rejection of what had hitherto been many of Labour’s defining policies. Out went public ownership, “tax and spend” welfare policies,
unilateral nuclear disarmament, and withdrawal from the European Union. In came private funds for public investment, a freeze on direct taxation, a welfare-to-work program, and a new pro-European ethical foreign policy.

Over time, New Labor under Blair traded increased spending on health and education for public service agreements linking resources to the achievement of rising performance targets. His government made extensive use of private funds for capital projects in the public sector, and increased the degree of market competition allowed between public service providers. Blair governments also developed social policies that traded rights for responsibilities, tackling social exclusion and child poverty while simultaneously toughening the criminal code, restricting immigration, and even punishing parents for the truancy of their children.

New Labour under Blair’s leadership played a crucial leadership role in the European response to the crisis in the Balkans, in the wake of which Blair spoke regularly of the need for the international community to be proactive to avoid crimes against humanity. Accordingly, he was the key architect of the broad coalition of support for the U.S.-led invasion of Afghanistan after the September 11, 2001, terrorist attacks; and, more controversially, he remained President George W. Bush’s main ally in the subsequent invasion of Iraq.

Blair’s final years in office were blighted by growing unease—in party circles and the wider electorate—with the consequences of privatization in the welfare sector and of his close alliance with the United States in Iraq. That unease was compounded by tensions with his chancellor of the exchequer over a deal, struck in 1994, that Blair would eventually cede the premiership to him. Relationships soured over time between the factions formed around each man, eventually forcing Blair reluctantly to announce that he would resign office in 2007.

BLAU, PETER M.
1918–2002

Peter M. Blau, the son of nonpracticing Jews, was born on February 7, 1918, the year that the Austro-Hungarian Empire fell. While in high school, Blau wrote articles for the underground socialist worker’s newspaper. Arrested at age 17, he was convicted of high treason and incarcerated by the Austrian fascist government. Meanwhile, Hitler was attempting to build the Nazi Party in Austria. That same year, 1936, the Austrian chancellor Kurt Schuschnigg conceded to Hitler that he would lift the ban on political activity, and so freed all political dissidents. Blau was allowed to finish high school.

Hitler and his troops officially took over power of Austria on March 13, 1938. Blau, having applied for a visa to emigrate, attempted to cross the Czech border. There the Nazi border patrol captured him and tortured and detained him for two months.

He lived in Prague until the Nazis invaded Czechoslovakia. Peter returned to visit his family for one night. He managed to go by the last train to France, where he was arrested and detained in a labor camp as an “enemy alien.” When his visa number came up, he waited in Le Havre for passage and had the good fortune to meet theologians who, to his great surprise and exceeding pleasure, gave him a refugee scholarship to attend Elmhurst College.

Blau attended Elmhurst College in Illinois, majoring in sociology. After completing his BA, Blau volunteered for the U.S. Army and served in the Normandy Invasion. He later learned that his family had been murdered in Auschwitz in May 1942, the same year he graduated from college.

His sociological writings amplify his conviction that democracy and human reason will prevail and his belief that one can judge a society by the extent that it fosters fairness and equality. He was profoundly skeptical of claims to personal authority, as distinct from ethical imperatives that emanated from widely shared norms. For his achievements, Blau received notable distinctions: election to the National Academy of Sciences, the American Philosophical Society, the American Academy of Arts and Sciences, and the presidency of the American Sociological Society. He taught at the University of Chicago, Columbia University, the State University of New York at Albany, Tianjin University, and the University of North
Carolina at Chapel Hill. Blau continued to enjoy teaching into his eighties.

Blau did pioneering work in four areas of sociology: organizations, social exchange, stratification, and intergroup relations. While his empirical work on organizations of many kinds was central to the development of organizational sociology, and Exchange and Power in Social Life (1964) continues to influence research on interpersonal interaction, here only the latter two areas are highlighted.

With his coauthor Otis Dudley Duncan, Blau, in The American Occupational Structure (1967), developed a radical new way of studying intergenerational social mobility. This work examined how social stratification occurs across generations and how factors such as education, occupation, and income determine an individual’s status to a lesser or greater degree than the parents’ status. This work stimulated an entire field of substantive research on occupation and mobility while developing new methods of structural equation modeling and processes of analyzing multidimensional data that remain in use.

Inequality and Heterogeneity (1977) and Crosscutting Social Circles, coauthored with Joseph Schwartz (1984), deal thematically with the sorts of social conditions in metropolitan communities that best bridge group differences. In Inequality and Heterogeneity, Blau lays out three parameters of communities: the extent to which communities are diverse along multiple dimensions; the extent to which there are prevailing inequalities; and the extent to which inequalities cut across group differences or are confounded with group differences. In Crosscutting Social Circles, Blau and Schwartz examine variation within 125 metropolitan communities, focusing on the extent to which inequalities are random or vary systematically across and within groups. Next they ask how such variation affects intergroup relations, as measured by marriage, and how heterogeneity promotes social equality.

In a career of more than fifty years, Blau played an important role in shaping the field of modern sociology. Many of the inquiries upon which he embarked became the basis for new fields and methodologies of mainstream sociology. His theories of social exchange, social structure, wealth distribution, diversity, and social reproduction are still widely used.

Blau conveyed in his writings a confidence that American institutions are inherently reasonable and that American educational institutions are open. He was optimistic that American society would be increasingly inclusive. As a private citizen, he was a socialist, supported dissenters and activists, and was impatient with the United States for being less than what he dreamed it to be in his early years. His political and social convictions are veiled in his work, as perhaps was the case with other social scientists of his generation.

Except in Exchange and Power in Social Life, which advances a number of sensitizing concepts, Blau used statistical techniques to answer the questions he posed. Heavily influenced by Karl Popper’s approach to scientific reasoning and falsification of hypotheses, much of Blau’s work illustrates how rigorous social science can be, while it masks his understanding of the important role that an author’s passion for truth and justice plays in scholarly pursuits.

BLINDER-OAXACA DECOMPOSITION TECHNIQUE

The Blinder-Oaxaca decomposition technique, or simply the Oaxaca decomposition, decomposes wage differentials into two components: a portion that arises because two comparison groups, on average, have different qualifica-
tions or credentials (e.g., years of schooling and experience in the labor market) when both groups receive the same treatment (explained component), and a portion that arises because one group is more favorably treated than the other given the same individual characteristics (unexplained component). The two portions are also called characteristics and coefficients effect using the terminology of regression analysis, which provides the basis of this decomposition technique. The coefficients effect is frequently interpreted as a measure of labor market discrimination. For a comprehensive review of issues related to labor market discrimination, see Joseph Altonji and Rebecca Blank (1999).

The Blinder-Oaxaca decomposition technique is named after two economists, Alan Blinder and Ronald Oaxaca, who introduced it to economic literature in the early 1970s. A similar version of this technique was explored in sociology during the late 1960s and early 1970s in order to examine sources of racial wage differentials (e.g., Duncan 1969; Althauser and Wigler 1972). The Blinder-Oaxaca decomposition technique has provided a practical way to apply economist Gary Becker’s (1971) definition of discrimination as unequal treatment among equivalent people due to race or gender. This decomposition technique has become a basic tool for studying racial and gender wage differentials and discrimination, and it has been allowed in court litigation on discrimination (Ashenfelter and Oaxaca 1987).

ILLUSTRATION

Suppose that only years of schooling affect the determination of wages for men and women. The illustration can be easily extended to a more complicated model in which several variables help determine wages. A linear equation is estimated using a regression technique in statistics. The two equations, the first for men and the second for women, are: $W_M = \alpha_M + \beta_M S_M + \epsilon_M$, and $W_F = \alpha_F + \beta_F S_F + \epsilon_F$, where $W$ is wages; $\alpha$ and $\beta$ are the intercept and the coefficient of years of schooling ($S$); $\epsilon$ is an error term; and subscript $M$ and $F$ are men and women, respectively. Economists usually use the natural logarithm of wages for $W$, while sociologists usually use level wages.

In order to examine sources of wage differentials between men and women, a counterfactual equation is constructed where women are treated as men. In other words, the intercept and coefficient in the women’s equation are replaced by those of the men’s equation. The counterfactual equation becomes $W'_{F} = \alpha_M + \beta_M S_F + \epsilon_F$. Wage differentials between men and women, on average, can be decomposed into a characteristics effect $W_M - W_F = \beta_M (S_M - S_F)$, that is, differences between men’s wages and counterfactual wages; and a coefficients effect $W_F - W_F = (\alpha_M - \alpha_F) + (\beta_M - \beta_F) S_F$, that is, differences between counterfactual wages and women’s wages. The Blinder-Oaxaca decomposition equation is: $W_M - W_F = [\beta_M (S_M - S_F)] + [(\alpha_M - \alpha_F) + (\beta_M - \beta_F) S_F]$.

Figure 1 shows the intuition behind the Blinder-Oaxaca decomposition technique. The diagram depicts a situation where men start off at higher wages without schooling (higher intercept) and receive a bigger payoff for each year of schooling (steeper slope). The wage differentials due to differences in intercepts and coefficients $W_F - W_F$, that is, the increases in wages when women are treated as men, are attributed to coefficients effect or discrimination. The remaining wage differentials $W_M - W_F$, the characteristics effect, arises because women have fewer years of schooling than men, although women are treated as men.

INTERPRETATION

The existence of discrimination and its measurement using the Blinder-Oaxaca decomposition technique has been a center of controversy. Those who believe that discrimination does not exist in the labor market or that the Blinder-Oaxaca decomposition technique overestimates the degree of discrimination point out that the wage equation cannot include all relevant variables measuring skills and individual productivity; hence, observationally equivalent people based on the characteristics in the wage equation may not be equivalent. In Figure 1, for example, the same years of schooling do not guarantee that both men and women are equally productive because men may be more motivated for work; therefore, the coefficients effect is not due to discrimination but to unobserved differences in productivity between men and women. As long as
people believe that the two comparison groups possess systematically different but difficult to observe characteristics, such as motivation, ability, and effort, they will argue that the measure of discrimination from the Blinder-Oaxaca decomposition technique is biased, and gross wage differentials can be explained by differences in skills and productivity between the two groups.

On the other hand, those who believe that there is prevalent discrimination or that the magnitude of discrimination is bigger than the coefficients effect itself argue that even differences in qualifications and credentials may be the result of premarket discrimination. In Figure 1, for example, it is possible that women were discouraged against pursuing higher education due to existing discriminatory barriers in the labor market (e.g., the glass ceiling) and elsewhere in the economy. Though current employers are not responsible for the different levels of schooling between men and women, society is. Therefore, those who believe in widespread discrimination in society may argue that the coefficients effect underestimates the magnitude of discrimination; hence, gross wage differentials may be an outcome of discrimination.

EXTENSIONS
In spite of the difficulties in interpreting the Blinder-Oaxaca decomposition equation, this decomposition technique has provided a starting point for studying racial and gender wage differentials and discrimination since its introduction in the early 1970s. Although the Blinder-Oaxaca decomposition technique was introduced to decompose racial and gender wage differentials, this technique is also suitable for studying changes in wages over time. In this case, the characteristics effect represents wage growth arising from changes in qualifications and credentials over time, and the coefficients effect shows changes in wages due to structural changes in wage determination over time. In principle, the Blinder-Oaxaca decomposition technique can be applied to decomposing differentials or changes of any continuous variable, such as hours of work. The flexibility of this technique is further demonstrated by extending it to decomposing differences or changes in binary choice variables, such as the labor-market participation rate (e.g., Yun 2004), and differences or changes in wage inequality measured with variances of log wages (e.g., Yun 2006). The Blinder-Oaxaca decomposition technique has been and will continue to be widely used in studying differences and changes in various socioeconomic variables due to its simplicity and flexibility in implementation, and the insights it offers.

BLOC VOTE
The term bloc voting (or block voting) refers to a set of voting systems used to elect several representatives from one constituency. Although there are significant variations in types of bloc voting, they all allow voters to cast multiple votes for one or more candidates and have the potential to result in several officials being elected based on one specific distribution of voter choices. Among the variables associated with different types of bloc voting are the number of votes available to each voter, the possibility of candidate ranking, and the decision rule for determining winners (Farrell 2001). These variables have consequences with regards to the advantages and disadvantages experienced by different aggregations of voters (see the excellent essays in Grofman and Lijphart 1986).

In plurality bloc voting, all candidates compete with one another. Each voter is allowed to cast one vote per candidate. The total number of votes available to a voter is the same as the number of seats to be filled. The candidates who are victorious are those who receive the highest number of votes. In some systems with plurality bloc vot-
ing, voters are required to cast all five of their votes for any one of their votes to count. This is sometimes referred to as a full ballot requirement. Plurality bloc voting allows one majority of voters, if it has a consistent set of preferences, to select all candidates to office. Such voting can be especially detrimental to the interests of a minority of voters who have preferences different from those of the majority.

Preferential bloc voting is a system in which voters are required to rank candidates by first-choice preference to the $n$th preference, with $n$ referring to the number of positions to be filled. No two candidates can receive the same preference ranking from any one voter. Candidates who receive the smallest number of first-choice rankings are eliminated in the first round of counting. The second-choice preferences of these voters are then counted as their first-choice preferences and distributed to the relevant candidates. The process of elimination of the candidates with the lowest first-choice preferences continues until the top $n$ redistributed first-choice candidates are identified.

Another type of bloc voting is referred to as cumulative voting. In this system, each voter is given a number of votes equal to the total number of positions to be filled. Voters, however, are able to express the intensity of their preferences for candidates by casting all of their votes for one candidate or otherwise distributing one, two, three, or four votes for one or more candidates. In such a system, tactical voting through strategic aggregation to enhance the probability that a voter’s first choice candidate(s) will be chosen is possible.

A related type of bloc voting is limited voting. In this system, voters are given a number of votes smaller than the total number of elected positions to be filled. Voters can either be required to cast one vote per candidate or group their votes as in casting all of their votes for one candidate or otherwise distributing one, two, three, or four votes for one or more candidates. In such a system, tactical voting through strategic aggregation to enhance the probability that a voter’s first choice candidate(s) will be chosen is possible.

Specific aggregations of voter choices, especially when two such groupings are in opposition to one another, are sometimes referred to as manifestations of a bloc vote. As discussed above, different types of bloc-voting systems can directly affect the chances that a specific type of block vote will appear.

BIBLIOGRAPHY

Luis Ricardo Fraga
continuing transmission of their superiority through their bloodlines.

At the peak period of the eugenics movement’s influence in the United States between 1910 and 1930, numerous federal and state laws were passed that reflected the obsession with purity of blood and the desire to regulate bloodlines. Existing antimiscegenation laws were strengthened and more rigorously enforced. Madison Grant (1865–1937), a leading eugenicist, wrote in *The Passing of the Great Race* (1916): “When it becomes thoroughly understood that the children of mixed marriages between contrasted races belong to the lower type, the importance of transmitting in unimpaired purity the blood inheritance of ages will be appreciated at its full value.”

Consequently, a recent cultural innovation—the “one drop” definition of nonwhiteness—was institutionalized into law in a number of American states. The one-drop doctrine held that a person with any nonwhite ancestry whatsoever in his or her ancestral bloodlines could not legally be classified as white. Virginia’s Racial Integrity Act of 1924 was the classic expression of one-drop doctrine, holding that “the term ‘white person’ shall apply only to such person as has no trace whatever of any blood other than Caucasian.” Virginia’s act prohibited interracial marriage, mandated that the race of every newborn be recorded and registered with the state government, and provided for a penalty of up to a year in prison for making a false report of racial identity.

Eugenic initiatives eventually moved beyond segregation and antimiscegenation laws. From the 1920s through the 1940s, a number of states in the United States set up programs to medically sterilize people defined as inferior—primarily on the basis of perceived mental disability—to ensure that they would not reproduce their traits in offspring. The Eugenics Record Office constructed pedigrees on thousands of families and determined that people who were mentally disabled came mostly from poor and minority families. Such findings only reinforced stereotypes of inferior bloodlines.

Eugenics principles were also invoked to justify anti-immigrant initiatives and exclusionary laws in the United States. Most notable was the Immigration Restriction Act of 1924, which was specifically intended to drastically reduce the flow of immigration of Italians and eastern European Jews, whom eugenicists considered to be of inferior stock. Australia, Canada, and New Zealand also passed exclusionary laws based on race, motivated by scientific racist notions of inferior bloodlines. Eugenics also took hold in some Latin American countries, where elites advocated increased immigration from Europe and the eradication of indigenous groups. The goal was to “whiten” society by reducing the number of nonwhite bloodlines. In Brazilian Portuguese this process was known as *branqueamento*. In Argentinean Spanish it was called *blanqueamiento*.

The most extreme form of eugenics took place in Nazi Germany, where Adolph Hitler’s obsession with blood purity led not only to antimiscegenation and sterilization programs but also an expansion into full-blown genocide against minority groups. The notion of a “Final Solution”—the extermination of inferior bloodlines—was not original to Hitler. It had already been entertained by Madison Grant, the prominent American eugenicist.

While scientific racism was significantly discredited in the late twentieth century, the use of blood as a metaphor for kinship remains firmly enshrined in popular discourse. The use of “blood quantum” persists in federal law, which mandates a requisite minimum of one-quarter Indian blood to qualify for some services reserved to American Indians. Most American Indian tribes have written their own laws mandating a minimum blood quantum as a requirement for tribal citizenship.

Some people have found ways to take advantage of American culture’s unresolved relationship with the notion of bloodlines. There are numerous cases in which an apparently white person claims an invisible “one drop” of black or Indian blood in order to gain access to minority entitlements. For example, in 1985 Boston firefighters Philip and Paul Malone were found guilty of “racial fraud” for falsely claiming a black grandmother in order to receive affirmative action employment advantages. More recently, Ward Churchill enjoyed a long career as a Cherokee academic and activist before being exposed by the Indian tribe in which he falsely claimed enrollment.

The archaic and scientifically discredited notion of blood as racial-ethnic identity persists in contemporary culture, bolstered by the historical echoes of pangenesis to be found in popular misunderstanding of DNA research. Many new business enterprises sprang up in the early twenty-first century that were designed to capitalize on this misconception, playing on the old theme of racial-ethnic bloodlines. For a fee, one can submit a DNA sample that firms purport to use to determine the percentages of various racial and ethnic identities in a person’s ancestral pedigree.

BLUE COLLAR AND WHITE COLLAR

Studies of the nature of blue-collar and white-collar work are conducted in a variety of social sciences, most notably economics and sociology. Although methodologies often differ in those disciplines—for example, sociologists are more likely to perform case studies, whereas economists generally use statistical analyses—the underlying phenomena are the same. Both fields study the decision-making behavior of workers, including how they choose an occupation and what constrains their choices. Those occupational choices affect their work lives, their social class, and the society as a whole. For instance, in 1945 the humorist and poet Ogden Nash observed, “People who work sitting down get paid more than people who work standing up.” Many people who work standing up are employed in blue-collar jobs, and most people who work sitting down are in white-collar occupations.

DEFINING BLUE-COLLAR AND WHITE-COLLAR WORK

The distinction between blue collar and white collar arose from the blue uniforms traditionally worn by men performing manual labor, in contrast to the white button-down shirts worn by men in professional occupations. These uniforms have become less prevalent with time, but it is possible to observe important differences between those occupational classifications. Blue-collar work can be unskilled, low-skilled, or highly skilled, ranging from relatively simple assembly-line manufacturing to the use of computerized equipment by automobile mechanics. Unskilled work does not require a great deal of training or human capital formation. Human capital is a worker’s productive capacity: his or her knowledge and skill in performing tasks. Common methods of acquiring human capital include formal schooling, apprenticeship programs, and on-the-job training. In addition, blue-collar jobs generally involve manual labor and physical tasks. Some of the occupations in this category are construction, maintenance, carpentry, assembly, plumbing and heating, typesetting, and truck driving.

Blue-collar workers often are paid an hourly rate and are eligible for overtime pay. Traditionally, many union jobs have been blue collar, and union bargaining power has contributed to higher wages for those workers.

Some aspects of blue-collar jobs are unpleasant, such as the risk associated with construction, fire fighting, and law enforcement. In general blue-collar work is often standardized and less autonomous than other types of work. Particularly in manufacturing, workers have seen periods of low job security for many reasons, including the substitutability of physical capital, which is the machinery and equipment used in production. Throughout the twentieth century production processes became much more capital-intensive as machines were introduced to perform tasks that previously had been done by workers. Another important characteristic is that blue-collar work has been done mostly by men. For instance, in 1999, 38 percent of male workers were employed in blue-collar occupations whereas only 9 percent of women were.

White-collar jobs generally require a fair amount of formal schooling, including college degrees ranging from associate’s degrees through professional degrees such as medicine and jurisprudence and academic degrees such as doctorates. Much of this white-collar work is performed sitting at a desk in an office environment, such as engineering, architecture, and bookkeeping. Many of these jobs are well paid, largely because of the amount of education and skill building required to enter these occupations. The acquisition of human capital also spurs greater income growth over time.

Highly educated workers who develop expertise receive promotions within the corporate hierarchy. White-collar jobs often require strong communication skills, either written or oral, for working in teams, communicating with clients or customers, and conveying information within the company. Many white-collar jobs, particularly professional and technical jobs such as accountant, law, and computer technology, are paid on a salaried basis. Hours worked per week tend to be very high in highly skilled white-collar jobs, with some employees spending more than sixty or seventy hours per week working. Corporate culture and promotion goals account for the long hours, and companies have an incentive to encourage salaried employees to work more hours because those workers are not eligible for overtime pay.
Throughout the twentieth century the majority of job growth was in the service sector. According to definitions from the U.S. Department of Labor, service occupations include health-care support jobs such as nursing and physical therapy; protective service jobs such as police and security work; food preparation; building and grounds maintenance; and personal services provided by hairstylists, child-care workers, flight attendants, and animal care workers. The service sector is not uniformly blue collar or white collar. For instance, washing dishes in a restaurant clearly involves manual labor and little training, but nurses are highly skilled professionals. Many of these workers are paid an hourly wage, but few are unionized. Some jobs, such as chefs, require not only strong communication skills but also the ability to manage a large staff.

**TRENDS IN BLUE-COLLAR AND WHITE-COLLAR JOBS**

In the mid-1950s well over 30 percent of American jobs were in manufacturing, and in the next fifty years that declined to 17 percent, whereas nongovernment services rose from 48 percent to 67 percent of all jobs. In the late twentieth century American employment in agriculture and manufacturing declined substantially, whereas construction and transportation jobs became more prevalent, revealing a new composition of blue-collar work in the United States. At the same time there have been vast increases in professional and technical work as well as work in the service sector and retail trade. There are also substantial differences in hourly pay rates across types of jobs. As is shown in the illustration, white-collar jobs are very well paid, with professional and technical workers earning approximately $30 per hour on average in 2005. In contrast, blue-collar workers received $15 on average, with those working in skilled craft and repair fields earning more and laborers earning less. The lowest-paid work was in the fastest-growing sector; service workers earned an average hourly wage of $11.

There are many sources of the changing mix of jobs from traditional blue-collar to white-collar work. One of the most important factors has been the steady increase in educational attainment in the U.S. population. In the early 1900s, 38,000 Americans earned bachelor's degrees. By 2000, well over one million Americans completed that level of education. Both men and women have pursued higher education in greater numbers. In 1940 just over 5 percent of men age twenty-five and over and nearly 4 percent of similarly aged women earned college degrees. By 2000 those proportions grew to 29 percent and 24 percent, respectively. In the early twenty-first century many students entered college because it appeared that a college degree was necessary for a good job: one with a high salary, good benefits, and pleasant working conditions. Therefore, the characteristics of the labor force (the labor
supply) have changed substantially. Though some blue-collar jobs are highly skilled, few require a college degree. The majority of highly educated workers seek and usually find white-collar jobs.

In basic labor economic theory it is expected that vast increases in the supply of a certain type of labor will coincide with downward pressure on wages. If companies have a seemingly endless stream of potential hires, there is an incentive to lower costs by offering lower wages. However, the data reveal that the earnings of college graduates have grown substantially so that the premium for degree recipients compared with those with only a high school diploma has remained high. Many researchers have focused on estimating the returns to formal schooling to better understand this dynamic. For example, in 1974 Jacob Mincer found that each year of schooling provides 10 percent higher earnings on average for white men. Furthermore, those returns to college education are greater in the United States than in most other Organization of Economic Cooperation and Development (OECD) countries, helping explain why increasing numbers of young people pursue those degrees and fewer work in manufacturing and trades.

In addition, the technology used in production has changed significantly. During the nineteenth and twentieth centuries electricity and internal combustion engines fueled the transition from a mostly agrarian society to a highly industrialized nation. Into the twenty-first century advances in telecommunications and computers have led workers away from manufacturing and into more service jobs. The use of technology has coincided with more productive workers, but there is also more capital that substitutes for workers, particularly in traditionally blue-collar jobs. Increased use of computers has led to consistently increasing demand for white-collar workers who use that physical capital in production, particularly employees who use personal computers at work.

It is assumed that companies consistently maximize profit and lower production costs. Common methods of cutting costs have had a disproportionately negative impact on blue-collar workers. In the 1970s and 1980s the United States saw many mass layoffs in manufacturing, most prevalently during times of recession, when many companies coped with deficient demand by closing plants. In some cases plants were moved out of the Northeast and Midwest and into the South for cheaper labor. In the 1990s layoffs were used more commonly to restructure firms and increase competitiveness. Some already profitable firms used layoffs to generate even more profit. Overall, in the last decades of the twentieth century over 10 percent of American jobs were lost through business contractions and plant closings.

Workers who have been laid off generally face a permanently lower standard of living. The workers who find a new job earn 15 to 40 percent lower wages than they had previously. One reason for this has been the prevalence of seniority-based raises in the manufacturing sector. Workers who displayed loyalty to the firm were rewarded with higher earnings and more vacation time during their long tenure. A worker who begins at a new plant therefore starts over with a lower wage. In addition, layoffs can cause persistent unemployment if workers have obsolete skills. This happened with many blue-collar jobs as the mix of production in the United States moved from manufacturing to service.

In the twenty-first century, firms continued to move production processes in order to become more profitable. Rather than move within the country, it is increasingly common to move offshore. This practice of offshoring is related to outsourcing. Outsourcing entails moving a business function (often administrative) out of the firm, and many companies do this with human resources or marketing. Offshoring occurs when a company moves some of the business (managerial, administrative, or production) to another country. Many jobs have been moved to Asia. In fact, after China entered the World Trade Organization in 2001, many manufacturing jobs were relocated there from the United States. The majority of American jobs lost to offshoring have been in blue-collar manufacturing, but white-collar workers have not been immune to this trend. For instance, advances in technology and computer support in India have led many American firms to employ white-collar workers there.

**PRIMARY AND SECONDARY LABOR MARKETS**

In the early twentieth century John Stuart Mill (1909) observed a lack of competition across segments of the labor market. He described one sector that required a fair amount of training and another that did not. Basically, the direct and indirect costs associated with the training kept some workers from competing in the market for well-paid jobs. Direct costs include out-of-pocket costs for training and the related supplies and materials. The indirect cost of forgone earnings arise because the time devoted to skill building is not devoted to work that earns a wage. Many in Mill’s class of “labourers” therefore were unable to take the time necessary to pursue higher-status occupations because they could not afford the associated costs. Thus, the labor market is seen as being segmented into two parts: a primary market and a secondary market.

Primary labor market jobs are characterized by good earnings, job security, a reasonable probability of promotion, good benefits, and agreeable working conditions such as autonomy and a pleasant working environment.
Many white-collar jobs match this description, and those jobs are plentiful and growing. Blue-collar jobs that are within the primary market appear in construction, mining, durable goods manufacturing, and transportation. In contrast, secondary labor market jobs have low earnings, few or no fringe benefits, high turnover, little job security, and few or no promotions. Many blue-collar and service jobs fit this description, and continuing increases in the service sector could create a larger secondary labor market. In this market, there are no clear returns to education and in some cases there are negative returns to experience.

OCCUPATION, INCOME INEQUALITY, AND SOCIAL MOBILITY

A person’s social class is defined by many factors, including income, wealth, education, location of residence, and family background. Occupation is also a main determinant of social class in terms of prestige (for example, surgeon versus construction worker), education required, and earnings received. White-collar jobs traditionally have paid well and carried more prestige than blue-collar jobs, contributing to common attributions of working-class or middle-class Americans. In the mid-twentieth century many working-class Americans had relatively good blue-collar primary market jobs in manufacturing. In contrast, working-class jobs around the year 2000 were more common in the service sector. Those secondary market jobs are not prestigious or well paid, in stark contrast to the growth of quality white-collar jobs for middle-class and upper-class Americans.

Concurrent with changes in class in the United States was the rise of income inequality throughout the twentieth century. To understand the nature of this inequality, it is valuable to make comparisons within the OECD countries, which include nations in North America, Europe, and some parts of Asia. Approaching the year 2000, the United States had the most unequal distribution of post-tax income. Many developing countries have even more inequality, but the best comparison group appears to consist of countries that are similar in industry mix and economic health: those in the OECD.

There are many sources of the unequal distribution of income in the United States. From the 1940s to the 1970s real mean wages rose, but in the next thirty-five years real wages were stagnant. The overall income distribution became more unequal, and more Americans lived in poverty. One of the commonly cited reasons for this is the lack of increases in the minimum wage over that period. Because minimum wages are raised only by government mandate, the legislature must vote on increases. No adjustments are made for purchasing power. If there are no legislated increases for a lengthy period, any wage gains are eroded by inflation (higher prices). At the same time more highly paid white-collar workers saw increased earnings, and in the United States the rich did become richer in the twentieth century.

Another factor explaining low wages for blue-collar workers is the decline in unionization. Compared with most West European countries, the United States has low union rates. In 2004 the percentage of workers covered by collective bargaining agreements was 68 percent in Germany, 33 percent in the United Kingdom, 93 percent in France, and only 14 percent in the United States. However, some strong U.S. unions remain in transportation, utilities, and construction jobs. In contrast, the growing service sector has few unions, and attempts to unionize those workers are generally unsuccessful. Labor economists debate the value of unions. Some cite unions as a potential source of gains for low-paid workers, whereas others believe that unions cause unfair restraints for businesses. When both blue-collar jobs and unions were more prevalent in the United States, the ratio of white-collar to blue-collar wages was lower than it became in the early twenty-first century; the premium to white-collar work grew as unions became weaker. In light of trends in wages and employment for white-collar, blue-collar, and service sector jobs, it appears that the U.S. income distribution is likely to continue expanding, with more inequality over time.

BIBLIOGRAPHY

Bluegrass is a highly stylized genre of American popular country music, ostensibly created in the late 1930s and early 1940s by the mandolinist Bill Monroe (1911–1996). Indeed, Monroe is the widely accepted Father of Bluegrass. However, the genre has diverse antecedents in the Scots-Irish fiddle tradition, “old-time” country music, country blues, small-group jazz performance, stereotyped “barn-dance” radio entertainment, and vaudeville. Monroe channeled and refined these influences into a tightly arranged, high-energy, radio-performance genre later termed bluegrass, which mediated between the rural and the newly urban on WSM radio’s widely broadcast Grand Ole Opry, a program that also functioned as a savvy popular representation of supposed “country ways” during a time of great urban relocation.

Today, due to its acoustic instrumentation, its highly foregrounded adherence to its own aesthetic tenets, and its widespread performance by passionate amateur musicians, bluegrass functions as a marker of musical authenticity in the world of country music more generally. This perceived authenticity is as much a part of bluegrass’s identity as any of its sonic features.

Following a dip in popularity due to the emergence of rock and roll in the 1950s, bluegrass has experienced periodic revivals, functioning as a badge of country legitimacy at points of overcommercialization or political uncertainty. It has thus become associated, on one hand, with radical populist movements (such as the so-called folk scare of the McCarthy era), as well as with proud nationalism, traditionalism, and social conservatism, on the other.

HISTORY

Bluegrass is inextricably linked to three groups of musicians living and performing in the Appalachian piedmont during the late 1930s. These groups played a common style that became an extremely popular genre in the 1940s and early 1950s. Mandolinist and singer Bill Monroe and his older brother had played so-called hillbilly music on the guitar and mandolin, touring professionally as the Monroe Brothers during the 1930s. After they parted ways, Bill Monroe founded a new band, the Blue Grass Boys, named after his home state of Kentucky (the Blue Grass State), and the band soon held a regular position on Nashville’s Grand Old Opry, one of country music’s most acclaimed radio shows. The classic sound of what came to be known as bluegrass crystallized in 1946 as the band’s repertoire and core group of musicians stabilized. This group included Earl Scruggs, who immediately popularized an impressive new technique for the five-string banjo, in which chords are arpeggiated and ornamented extremely rapidly with three picking fingers (rather than strummed or played more melodically). The appearance of this new banjo style on the radio helped generate a wave of popular enthusiasm for the Blue Grass Boys across the Southeast.

Citing fatigue, Scruggs and vocalist/guitarist Lester Flatt (1914–1979) left the band at the height of its popularity, and soon formed their own group, the Foggy Mountain Boys, the second of the classic bluegrass triumvirate. Trading on Scruggs’s vaunted virtuosity and Flatt’s smooth vocal style and engaging stage presence, Flatt and Scruggs quickly achieved widespread success. The third of these widely acknowledged innovators was the Stanley Brothers, Ralph (b. 1927) and Carter (1925–1966), who initially imitated the sound of Monroe’s Blue Grass Boys, whom they had heard on the radio and on records. However, the Stanley Brothers soon began to emphasize older musical traditions, such as balladry, thus cementing history and nostalgia as integral to the bluegrass aesthetic.

Despite its origins as a new sort of sophisticated country music (the Blue Grass Boys all wore unconventionally formal attire), and its dependence on modern mass media for its dissemination and popularity, the core of bluegrass’s identity has come to rely on concepts of nostalgic authenticity, linked to ostensibly bygone ideals of purity, straightforwardness, and honesty. These tropes of purity are expressed lyrically, through themes that emphasize labor, family, nostalgia, pathos, regret, and grim prospects, and musically through the use of string instruments that do not require “modern” electricity (though the sounds of these instruments are commonly electrically amplified). This instrumentation typically includes the five-string banjo, mandolin, fiddle (violin), steel-string acoustic guitar, upright (double) bass, and often the resophonic guitar (Dobro), with the occasional pragmatic addition of light percussion or electric bass.

PERFORMANCE

Professional bluegrass performance is mostly executed on summer tours, supported by an informal network of locally organized festivals. These festivals specialize in bluegrass, though other closely related genres may be rep-
resented. Local groups are typically given earlier slots on festival schedules, and participating professional and amateur musicians commonly congregate and play before and after performances. Casual “parking-lot picking” on festival grounds is an important aspect of these events, as amateur performance is a highly valued aspect of bluegrass music. Amateur performance is also widely sustained through informally organized (but highly regular) jam sessions and “pickin’ parties.”

GENRE FEATURES

Bluegrass has proven to be a remarkably robust genre, maintaining a generic coherence over many decades. It is notable for its foregrounded adherence to its own genre rules, commonly stated among practitioners thus: “If it don’t have X, it ain’t bluegrass.” However, it exists both as a generic template that can be applied to other kinds of music (a successful series known as Pickin’ On markets bluegrass-style versions of the music of nonbluegrass artists, such as Pickin’ on Dylan, Pickin’ on R.E.M.), as well as a flexible paradigm that can absorb other musical parameters without losing its identity (for example, Pete Wernick’s 2002 recording Live Five interpolates clarinet and vibraphone).

Emerging from vernacular musical traditions, the bulk of the bluegrass repertoire has typically been written in keys that allow for playing in open or first positions, utilizing open strings for accompanying drones and full, ringing chords or double (or triple) stops. However, fast tempi and tight arrangements have bred a sense of virtuosic pride into bluegrass performers, and many pieces written in formerly “awkward” keys are now commonplace.

Instrumentals are commonly written as tunes to be repeated with different musicians playing the melody in sequence. Typical repeatable forms are AABB or AABA. Vocal pieces are commonly in verse/chorus A(A)BABA form, though strophic ballads, true to bluegrass’s nostalgic bent, are also common (AA ... A). As noted above, however, the pride of bluegrass musicians in their technical abilities has allowed for many idiosyncratic song forms.

BLUES

The blues, a term coined by the writer Washington Irving in 1807, is defined by Webster’s Dictionary as a type of music “marked by recurrent minor intervals”—so-called blue notes—and by “melancholy lyrics.” These lyrics reflect the oppression experienced by people of African descent in the United States: slavery, prison, chain gangs, and the indignities of the Jim Crow era.

Blues is a typically American music with its earliest roots in African forms. It originated with the slaves that were brought over from West Africa. The contemporary Malian musician Ali Farka Touré considers blues to be the type of music most similar to his own; specifically, Touré hears echoes of Tamacheq music in the music of blues artists such as John Lee Hooker. Because slaves were forbidden to use drums, they turned to traditional African “ring shout” and created rhythms with their hands and feet. Through ring shouts slaves worshipping in “praise houses” connected the newly imposed Christianity to their African roots. “Field hollers,” produced by slaves as a means of communication, were another early vocal style that influenced the blues. Work songs sung by prison road gangs also highly influenced the blues in its early days. The art of storytelling is another important element of the blues. Lyrical, the blues ranges from forms based on short rhyming verses to songs using only one or two repeated phrases.

Over time, the blues evolved from a parochial folk form to a worldwide language. The influence of the blues can be found in most forms of popular music, including jazz, country, and rock and roll. The lines between blues and jazz are often blurred. Kansas City jazz, for example, is known for its bluesy sound. Certain artists, such as Charles Brown, Jimmy Smith, Jimmy McGriff, and Mose Allison—all masters of the keyboard—make music that is hard to categorize as either purely jazz or purely blues. Likewise, gospel is closely related to the blues. The music of the “father of gospel,” Thomas A. Dorsey, was a blend of blues and spirituals.

Ashenafi Kebede (1982) assigns the blues to four categories: country blues, city blues, urban blues, and racial blues. Country blues was traditionally performed by street musicians without any formal training. City blues is a standardized version of country blues. During the 1940s, as a result of the impact of communication media, city blues evolved into the more commercialized and formalized urban blues, a style characterized by big band accompaniment, modern amplification devices, and new instruments like the saxophone and electric guitar. Racial blues are songs based on racial distinctions between blacks and whites.

The great composer and musician W. C. Handy (1873–1958) was one of the first to bring blues into the
Blumer, Herbert

1900–1987

Herbert George Blumer earned his doctorate in 1928 at the University of Chicago and went on to teach there until 1951. He later became the founding chair of the Department of Sociology at the University of California, Berkeley. In 1983 the American Sociological Association honored him with its Career of Distinguished Scholarship Award, acknowledging the importance of his codification of the fundamental theoretical and methodological tenets of the sociological perspective that he called symbolic interactionism.

While it is not possible to capture the great range and significance of his contributions to the study of human group life in a single quotation, this oft-cited passage from his most influential and widely read work, Symbolic Interaction: Perspective and Method, sets out the cardinal premises of symbolic interactionism and the central message of his scholarship:

While the blues was historically an African American form, in the early 1960s the urban bluesmen were “discovered” by young white American and European musicians. Prior to this discovery, black blues artists had been unable to reach a white audience. Among the best-known English blues artists are Eric Clapton and John Mayall; celebrated white American bluesmen include Paul Butterfield,

Charlie Musselwhite, Johnny Winter, and Stevie Ray Vaughan. All were heavily influenced by the great African American blues artists.

At the start of the twenty-first century, the blues is still going strong, as evidenced by the numerous national and international blues societies, publications, and festivals.

The first premise is that human beings act toward things on the basis of the meanings that the things have for them. The second premise is that the meaning of such things is derived from, or arises out of, the social interaction that one has with one’s fellows. The third premise is that these meanings are handled in, and modified through, an interpretative process used by the person in dealing with the things he encounters (Blumer 1969, p. 2).

Accordingly, individual and collective actions of any scale or complexity reflect the meanings that people assign to things, as these meanings emerge in and are transformed within the context of human group life. Blumer incorporated these assumptions into his vision of social life as an ongoing stream of situations handled by people through self-indication and definition.

Blumer synthesized the pragmatist philosophy of George Herbert Mead (1863–1931) with Charles Horton Cooley’s (1846–1929) notion of sympathetic introspection, particularly as it informs contemporary ethnography, to develop a sociologically focused approach to the study of human lived experience. In opposition to behaviorist, structuralist, and positivist views that have dominated the social sciences, Blumer championed using an interpretivist perspective when examining social life. He contended that theoretical and methodological approaches to the study of human behavior must recognize human beings as thinking, acting, and interacting entities and must, therefore, employ concepts that authentically represent the humanly known, socially created, and experienced world.

Blumer’s pioneering sociological perspective informed his analysis of a broad array of subjects including collective behavior, social movements, fashion, social change, social problems, industrial and labor relations, public opinion, morale, industrialization, public sector social science research, social psychology, and race relations. And, because his rendition of symbolic interactionism invariably portrays people as possessing agency, as reflective interactive participants in community life, he routinely called into question analyses of social life that rely on more stereotypical factors-oriented approaches.

Although Blumer’s 1958 article “Race Prejudice as a Sense of Group Position” challenges psychological and psychoanalytic explanations of race relations by emphasizing social processes entailed in conflict, institutionalized power relations, and collective definitions of the situation, his most consequential contribution to the study of intergroup relations was his 1971 article “Social Problems as Collective Behavior.”

BOAS, FRANZ
1858–1942

Franz Boas is recognized widely as the “father of American anthropology” because at Columbia University he trained a generation of graduate students who transformed an assortment of classificatory schemes based on evolutionary hierarchies into a comprehensive four-field discipline that integrated linguistics and archaeology with biological anthropology and cultural anthropology. In addition, Boas was a pioneering public intellectual who used science to challenge ideas of racial inferiority and the barbarism of certain cultures by employing empirical research to demonstrate how racism, the environment, and the history of specific cultures can explain difference and diversity.

EDUCATION AND WORKS
Born in Minden, Germany, Boas attended universities in Heidelberg, Bonn, and Kiel. His first academic appointment was in 1888 at Clark University, where he initiated a comprehensive research program that began to challenge
some of the basic assumptions of racial categories; those efforts culminated in a major project for the U.S. Immigration Commission and were published as *Changes in Bodily Form of Descendants of Immigrants* (1912). In that work Boas demonstrated that the environment plays a significant role in determining physical attributes, such as head size, that often were used at that time to demarcate racial difference.

During the late nineteenth century racial categories were classified by head size, body type, and skin color and were linked to behavior, language, customs, and morality. Boas asserted that body type and race are discrete modalities and are not linked to customs and belief systems. Furthermore, he argued, one could not demarcate distinct racial categories accurately and cultures could not be rank-ordered within the then-current terminology as savage, barbarian, and civilized. His most definitive treatment of these issues was in *The Mind of Primitive Man* (1911).

The foundation of that theoretical paradigm shift in the natural and social sciences was Boas's understanding that cultures and languages should be evaluated in the context of their own complex histories and on their own terms as opposed to analyzing societies in terms of stages of evolution along a singular road to a civilization or an apex of culture. Much of Boas's research and theory was grounded in empiricism, participant observation, and detailed transcription of grammars, myths, kinship terminology, and folklore, using the interpretive framework of the people he studied.

Opposed to imposing an analytical framework on a set of traits and tendencies to deduce laws of culture, Boas instead relied on the use of inductive methods to identify patterns in process and the diffusion of material culture or folkloric themes through time and between cultural groups. Most of his ethnographic fieldwork was focused on the complex indigenous communities of the Pacific Northwest. To achieve such exhaustive empirical studies Boas relied on key informants who served as important collaborators. One of the most influential of those collaborators was George Hunt (Lingít), who was raised among the Kwakwaka'wakw near Fort Rupert on Vancouver Island in British Columbia. Hunt was instrumental in helping Boas develop his definitive work on the Kwakiutl language and kinship.

In 1896 Boas began to lecture at Columbia University, and in 1899 he became its first professor of anthropology. At that university he developed the distinctly North American four-field approach to anthropology. He also helped curate anthropological exhibits at the American Museum of Natural History, where he worked from 1895 to 1905.

In addition to his ethnographic work Boas conducted detailed studies on the growth of children and the head sizes of immigrants. Between 1908 and 1910 he measured 18,000 adults and children, using the data to produce the study *Changes in Bodily Forms of Descendants of Immigrants* (1912). Although there has been debate about the validity of his data, that study, among others Boas conducted, demonstrated that the physical metrics used to demonstrate the putative superiority and inferiority of racial groups and thus justify Jim Crow segregation and selective immigration restrictions were erroneous. African American intellectuals and early civil rights organizations welcomed the new science, and Boas actively supported the National Association for the Advancement of Colored People and formed lasting working relationships with scholars such as Carter G. Woodson (1875–1950) and W. E. B. Du Bois. Boas was also a champion of peace, academic freedom, and equal opportunity.

### INFLUENCE

Perhaps Boas's greatest contribution to the field of anthropology was inspiring and training a generation of students who shaped the field in enduring ways. Many were women, and several were people of color. The list of students and colleagues whom Boas influenced at Columbia is impressive. Alfred Kroeber and Robert Lowie established the anthropology program at the University of California at Berkeley, Edward Sapir (1884–1935) and Faye-Cooper Cole (1881–1961) developed anthropology at University of Chicago, Leslie Spier (1893–1961) brought anthropology to the University of Washington, and Melville J. Herskovitz organized an anthropology program at Northwestern. Other notable students include Margaret Mead, Ruth Benedict, and Zora Neale Hurston whose collective influence on American science and letters is much greater than his male students. Others included William Jones (1871–1909), a member of the Fox Nation and one of the first American Indian anthropologists; the Mexican anthropologist Manuel Gamio (1883–1960); the African American ethnographer Eugene King (1898–1981); Elsie Clews Parsons (1875–1945); Gene Weltfish (1902–1980); Gladys Reichard (1893–1955); and Alexander Goldenweiser (1880–1940). Together they went well beyond Boas's careful empirical studies to develop an understanding that cultures are dynamic and fluid, language is an integral aspect of culture that has internal structures and logics, history and ethnographic methods are central facets of anthropological research, and racial categories are scientifically untenable bases of analysis.

The systematic study of body image began in the 1960s when psychiatrist Hilde Bruch (1904–1984) posited that negative body image was a causal mechanism in the development of anorexia nervosa. Since that time, numerous studies have linked body-image disturbance to the development of eating disorders and the onset of dieting. Although studies of non-treatment-seeking obese individuals indicate that there is no difference in the prevalence of psychopathology among obese and normal weight individuals, obese people consistently report higher dissatisfaction with body image and physical appearance than normal weight individuals (Rosen 2002). Furthermore, negative body image in treatment-seeking obese individuals is associated with psychological distress (Friedman et al. 2002).

A renewed interest in body image arose in the 1980s. Judith Rodin and colleagues (1984) described the widespread concerns about body image among women as a “normative discontent.” This early research found a greater risk for body dissatisfaction among Caucasian women than men and women of color. Among females body-image dissatisfaction tends to be associated with the desire to lose weight, whereas among males body-image dissatisfaction is often associated with the desire to increase muscularity (McCready and Sasse 2000). Recent evidence suggests that ethnic differences in body-image dissatisfaction may be decreasing, although more research is needed (Shaw et al. 2004). Sexual orientation is another factor that is associated with body-image concerns: homosexual males are more likely to report body dissatisfaction than heterosexual males and homosexual women (Siever 1994).

Body-image concerns typically surface with the onset of puberty. Adolescence may be an especially challenging time for girls because the thin-body ideal is inconsistent with normal pubertal changes such as increased body fat (Bearman et al., 2006) In contrast, muscle development associated with puberty in boys is more consistent with the athletic male body ideal. Normal growth and gender-specific social ideals may help explain the discrepancy in the prevalence of body dissatisfaction between females and males.

Interpersonal relationships during adolescence also appear to be related to negative body image. In particular, being teased about one's body by peers and family is associated with body-image disturbance (Keery et al. 2005; Eisenberg et al. 2003). Perceived pressure about weight from friends and parents also may play a strong role in promoting body dissatisfaction (McCabe and Ricciardelli 2005). Sociocultural theories suggest that the cultural emphasis on female appearance, especially weight, contributes to the development of body-image dissatisfaction. The impact of the mass media on body image seems to
depend on the extent to which individuals internalize messages about beauty (Stice and Whitenton 2002).

BODDY MASS INDEX

Body Mass Index, or BMI, is a common measure of weight status in adults. BMI can be calculated by multiplying weight in pounds by 703, divided by height in inches squared, and it serves as an index of weight-for-height measured in kg/m². BMI indicates overweight between 30 kg/m² and 34.9 kg/m²; obesity between 35 kg/m² and 39.9 kg/m²; and clinically severe obesity above 40 kg/m². BMI is an indirect estimate of body fat and is highly correlated with body fat at about .7 (Gray and Fujioka 1991). Although there are more accurate measures of body fat (e.g., underwater weighing and DXA), they are more expensive, inaccessible, and cumbersome compared to BMI (Blew et al. 2002). The widespread use of BMI is likely due to its cost-effectiveness and ease of calculation.

The measurement and definition of overweight and obesity has varied over time. For much of the twentieth century, physicians and researchers referenced Metropolitan Life Insurance Company (MLIC) tables, which recommended ideal weight-for-height. The MLIC tables suffered from limitations (e.g., unstandardized and inaccurate measurement protocols) that prompted the government to adjust the weight guidelines in the 1980s (Kuczmarski and Flegal 2000). In the mid-1980s BMI became the preferred measurement of weight status, and recommendations were based upon data from national epidemiological surveys such as the National Health and Nutrition Examination Survey. BMI emerged in the first annual federal report on the prevalence of obesity in the United States, and a National Institutes of Health (NIH) panel defined overweight in terms of sex-specific BMI cutoffs (Kuczmarski and Flegal 2000; National Center for Health Statistics 1984; National Institutes of Health Consensus Development Panel 1985).

The current classification system adopted by the National Heart, Lung, and Blood Institute uses BMI to determine weight category. Classification of weight status is important because numerous medical comorbidities are associated with increased BMI. The BMI cutoff for overweight has decreased over time from 30 to 27, and most recently 25. Further, BMI provides a relative index of growth stunting, a condition that may result in significant developmental delays and adverse physiological effects (Dickerson 2003).

Kelli Friedman

Erin E. Martinez
There is empirical evidence that BMI may be more predictive of body fatness in certain subgroups (e.g., younger adults, Caucasians) than others (Baumgartner, Heymsfield, and Roche 1995; Gallagher et al. 1996). Thus, two individuals with an identical BMI may have a different percentage of body fat depending on factors such as age, gender, body shape, and ethnicity (Prentice and Jebb 2001). BMI also overestimates body fat in persons who are very muscular (e.g., athletes), does not distinguish lean mass (muscle and bone) from fat mass, and does not determine the distribution of body fat. In children, BMI must be adjusted for growth. Despite these shortcomings, BMI classifications are still valuable for research and health care.

BMI is used to diagnose and make treatment recommendations. Epidemiological studies measure BMI to identify population trends in growth retardation and obesity along with associated adverse health consequences. Mounting evidence indicates an increased risk of mortality among obese individuals. Increased BMI has been associated with medical comorbidities including cardiovascular disease, reduced fertility, sleep apnea, metabolic syndrome, hypertension, type 2 diabetes, and certain cancers. In addition to medical risks, evidence suggests that there is a powerful social stigma associated with obesity. Discrimination affects overweight individuals in numerous facets of life, including employment, education, and psychological well-being (Friedman et al. 2005; Puhl and Brownell 2003).

BOER WAR

The Boer War (or Anglo-Boer War) was a conflict in which the British Empire fought the forces of two “Boer Republics” from 1899 to 1902 in southern Africa. The
Boers lost the war, but resistance gained them concessions even in defeat. One of many conflicts that heightened international tensions before 1914, the war accelerated patterns of violence that came to mark twentieth-century warfare, especially violence toward civilians.

The “Boer” population—mostly of Dutch Calvinist background—originated with a Dutch East India Company colony planted at the Cape of Good Hope in the seventeenth century. Britain acquired the Cape Colony during the Napoleonic Wars. After clashes with the British administration, many settlers migrated northward in the “Great Trek” between 1835 and 1841, establishing two “Boer republics”: the South African Republic (or the Transvaal) and the Orange Free State. The term Boer means “farmer” in Dutch and in the related language that developed among these settlers, which today is called Afrikaans.

The earlier war associated with the terms Boer War and Anglo-Boer War (1880–1881) was the result of British attempts to establish control over the republics. The British lost militarily but gained Boer agreement to nominal British rule over the autonomous republics. The conflict more commonly called the Boer War began in 1899 and was connected to the discovery of gold in the territory of the Transvaal in 1886. Europeans poured in to run the mines and recruit African labor. In the nineties, colonial authorities pushed to gain the vote for resident “foreigners” (uitlanders), a measure that would have enabled the uitlanders to vote the republics into dissolution. Transvaal President Paul Kruger (1825–1902) opposed the plan vehemently. The Jameson Raid of 1895, sponsored by Cecil Rhodes (1853–1902; Cape Colony premier), was an effort to establish British control by force. After the defeat of the filibuster, German Emperor Wilhelm II (1859–1941) sent a telegram congratulating Kruger, to the irritation of the British. More concretely, the Germans also sent arms to the Boers in an attempt to counter their imperial rival, Britain.

Assisted by mining interests, in the late 1890s British Colonial Secretary Joseph Chamberlain (1836–1914) and British High Commissioner Sir Alfred Milner (1854–1925) pressured the republics to give full citizenship to all resident British subjects. An attempt at reconciliation at the Bloemfontein Conference in mid-1899 failed, and the sides exchanged ultimata. The Boers struck first, invading the Cape Colony and Natal with a force based on the militia-like pattern of Boer defense, the commando system. The keys to their powerful blows against professional British units were expert marksmanship, good weapons, and mobility (mostly on horseback). From October 1899 to February 1900, Boer forces enjoyed success, defeating larger British units in a series of conventional battles, climaxed by the Battle of Spioenkop (earlier, Spion Kop), where British troops failed to carry the Boer lines after assaulting them for two days and losing 1,683 men, compared to 198 on the part of the Boers.

The tide of the war turned in February 1900, when British Field Marshall Lord Frederick Sleigh Roberts (1832–1914) arrived with reinforcements. Though the British continued to sustain high losses, they were now able to overpower Boer forces, which retreated back to the Transvaal and the Orange Free State. Roberts followed and captured the Boer capitals by early June. The largest remaining Boer force was defeated in August 1900. Yet the Boers had already decided to move away from conventional warfare and adopt a guerrilla war of raids and ambush; by June this campaign was in full swing. Several capable commanders emerged, especially Christiana de Wet (1854–1922) and Jan Smuts (1870–1950). The British columns were deadly, but the Boer commandos were frequently elsewhere by the time the British were ready to strike.

Hence, although they nominally occupied the republics, British forces seemed stymied. Soon 250,000 British troops were engaged, but this number still represented a relatively low ratio of troops to area: The territory of the Transvaal alone (111,196 square miles) almost equaled that of the British Isles. The British military compensated for this low density of troops with a network of hundreds of “blockhouses,” outpost structures giving protection to small garrisons and linked by barbed-wire fences, designed to disrupt Boer movements.

Lord Roberts resigned in November 1900 because of sickness, and Herbert Lord Kitchener (1850–1916) took command. Kitchener intensified the “scorched-earth” policy that Roberts had already begun, which paralleled similar strategies in other contemporary colonial conflicts. His plan was to destroy Boer homes and crops and appropriate their livestock to deny the commandos food, supplies, and hiding places; in two years the army burned some 30,000 Boer dwellings.

A byproduct of the “scorched-earth” policy was the creation of “concentration camps” to house those made homeless. Among the refugees were Boer women, children, and elderly, but also black Africans associated with Boer farming economies, or simply those displaced by military operations. British commanders also hoped that holding the refugees in tent camps surrounded by barbed wire, with limited food and rough hygiene, would bring about Boer surrender. Kitchener built forty concentration camps containing 116,000 prisoners, most of them women and children. Malnutrition and disease killed a high percentage. In a year and a half, well over 26,000 Afrikaners died, over 20,000 of them children under sixteen. The British also rounded up black Africans into camps, where as many as 17,000 died of disease and poor...
conditions. Some 12,000 of those seem to have been children. The total of black African deaths caused by the war is unknown. Nearly all the relevant mortality figures have been disputed, but it is not in dispute that the primary killer, even in the case of military deaths, was disease.

Whatever the effect of British tactics on the outcome of the war, it is clear that the Boers did not have the resources to fight on indefinitely. Several larger-scale battles in 1902 led to losses that thinned the already sparse commando ranks. The Boers surrendered in the spring of 1902, and the war ended with the Treaty of Vereeniging, signed on May 31, 1902. The two republics became undisputed British possessions, but they emerged with considerable autonomy, allowing for self-government and continued use of the Dutch (later redefined as Afrikaans) language in schools, courts, and other institutions. The British agreed to pay a large sum for reconstruction in compensation for war damage. On the question of the enfranchisement of black Africans in the region, the treaty stipulated that no discussions of the issue would be held until after the region had been granted self-government.

Historians generally understand the war to have promoted and accelerated social trends marginalizing black African and racially mixed populations in South Africa. Hence, the institutionalization of apartheid (separateness) after World War II is seen as a later stage in developments resulting from the settlement of the Boer War. New legal restrictions based on race appeared in South Africa in the following decades. The Boer War also seems to have set in motion or intensified dislocation and the breakup of traditional cohesions among black South African ethnic groups, trends that shaped later racial relations in South Africa.

The war was an international affair, particularly on the British side. Some 22,000 soldiers of the British Empire died, and hundreds of thousands served. Yet, thousands were not from the British Isles. Africans served in various capacities. Many Indians living in South Africa likewise served in the war (Mohandas Gandhi [1869-1948] was a stretcher-bearer in the volunteer Indian Ambulance Corps). Australia’s involvement in the Boer War became a significant part of Australian history and identity. Over 10,000 Australians served in Australian units alone, and many others in British units. Some 500 Australians died in the war, about half from disease. Nearly 7,500 Canadians served, with deaths totaling 219, and New Zealand sent some 6,500 troops, with 229 resulting deaths. The war was, after all, an imperial effort.

The unity implied by these contributions did not reflect universal support back home. In Britain pacifists, liberals, socialists, and others were outspoken opponents of the war. Among the best known was political activist Emily Hobhouse (1860–1926). Opposing the war force-fully, she organized the Relief Fund for South African Women and Children in 1900 and traveled to South Africa to visit the concentration camps. Her efforts led to official inquiries and eventually a lowering of the mortality rates in the camps. Another prominent opponent was economist John A. Hobson (1858–1940), who produced a critique that far outlasted the events he observed. Covering the war for the Manchester Guardian, he wrote in The South African War: Causes and Effects (1900) that the war had been foisted on Britain by a “small confed eracy of international mine-owners and speculators” lobbying for the war to support their own investments in South Africa. Hobson later generalized these and other arguments to apply to the whole of European imperialism in Imperialism (1902). Vladimir I. Lenin (1870–1924) adapted some of Hobson’s ideas in writing Imperialism: The Highest Stage of Capitalism (1916).

**BOLSHEVISM**

The Bolsheviks were the party that V. I. Lenin created in exile in 1903 and then used to conduct the successful Bolshevik Revolution in November 1917. Bolshevism is a
western intellectual construct that helped to focus a debate on whether the Stalinist system was the logical consequence of Lenin's principles, or whether Bolshevism was a more subtle and complex phenomenon with which Stalinism had only a tangential relationship.

Lenin firmly rejected the growing movement that promoted a peaceful evolution of socialism. In 1902 he split with his closest revolutionary allies over control of their newspaper, Iskra, and over who could join their party: Lenin insisted that the party membership be limited to those who accepted strict party discipline and the duty to work actively for the revolution. The opposition had a more western view of a decentralized party that accepted anyone who would support the party program and pay dues. When it was put to a vote, Lenin had a (narrow) majority, so he called his supporters the Bolsheviki (from bolshinstvo, “majority”) and his opponents the Mensheviki (from menshinstvo, “minority”).

The tsar responded to the Revolution of 1905 by creating a limited parliament, the Duma, and expanding political rights. Lenin was willing to use these institutions only tactically, to promote revolution, but the Mensheviki gradually became a western, social-democratic party that saw capitalism as the next long-term stage in Russian history. Other issues became politically crucial. Lenin's centralized party implied a strong Russian empire, whereas the Mensheviki's position implied a looser one. Lenin's rigid orthodoxy implied that modern western culture was the tool of bourgeois rule, and his rejection of cooperation with liberals appealed to those who rejected westernization.

When Russia's failure in World War I led to the overthrow of the tsar in March 1917, plunging Russia into chaos, Lenin rallied a large coalition—his traditional worker-peasant support, intellectual radicals, and antiwar forces, including some in the military. In these conditions, the party was opened to all applicants, and this continued during the civil war. There is still debate about whether the broader membership of the party, together with Lenin's toleration of private agriculture and trade in the New Economic Policy, would have produced a more tolerant one-party system in the Soviet Union had Lenin or an appropriate successor been chosen. Some historians contend that Lenin's massive purge of party members from 1921 to 1923 and his decision to rule through the party apparatus under Stalin's control suggest that the openness in 1917 and during the civil war was an aberration. The answer is unknowable.

During the late Soviet period, reformers painted a softer picture of Lenin in order to claim they were true Leninists: The modern generation is less concerned about “what if” questions about Lenin and more likely to focus on Bolshevism's appeals. The successes of both Lenin and Stalin rested on the peasants and first-generation workers who flowed into the cities in massive numbers. Around the world, Communism was most successful at that stage of history, and it collapsed in Russia when the nation reached a new stage of development. In other countries, however, frightened peasants moving to the cities continued to be attracted to leaders who appealed to their grievances with a rigid doctrine, a centralized control of disorder, and antiwesternism. Other doctrines that appealed to the same social forces took hold, and religious fundamentalism was the first of them.

BONACICH, EDNA

Edna Bonacich is one of the leading scholars on race and class in the United States. Her work focuses on social inequality, labor, immigration, sweatshops, and global production. She gained prominence in the 1970s based on the publication of three seminal articles in the American Sociological Review. Bonacich later coauthored books on middlemen minorities and immigrant entrepreneurs (with John Modell and Ivan Light, respectively) and coedited two volumes on Asian immigration. She also coedited a book on the apparel industry in the Pacific Rim region and coauthored (with Richard Appelbaum) Behind the Label (2000), an award-winning book that examines the Los Angeles garment industry and the resurgence of sweatshop labor.

Bonacich was born in Connecticut in 1940. She lived in New York City for several years before moving with her father (a Jewish reform rabbi), mother, and two siblings to South Africa in 1950. Witnessing the “world's most racist regime” first-hand profoundly influenced her career as a sociologist. While living in South Africa, she joined a Zionist youth organization that focused on establishing collective farms (kibbutzim) in Israel. After graduating from high school, she lived in Israel for a year, living on
two separate kibbutzim, before she became disillusioned with Zionism (Bonacich 2005). She eventually moved back to South Africa and became a student at the University of Natal, where she graduated with a Bachelor’s of Social Science degree in sociology, psychology, and English in 1961. She obtained her master’s and doctoral degrees in sociology from Harvard University in 1966 and 1969, respectively. In 1970 she started working in the Sociology Department at the University of California, Riverside (UCR), and she stayed there until her retirement in 2006.

Bonacich’s experiences in South Africa and Israel strongly shaped her views about race and class. Those views included the well-known but controversial claim that racism and capitalism emerged nearly simultaneously, and that both systems of inequality should therefore be concurrently challenged and abolished. Split labor markets (in which one group of workers is paid more than another) and middlemen minorities prevented these changes from taking place, however. Rather than create coalitions with mostly lower-paid workers of color, higher-paid white workers have typically favored exclusionary legislation in the United States. Meanwhile, both white workers and workers of color have often singled out middlemen minorities, who occupy an intermediate strata (or “buffer”) between capital and labor. These middlemen minorities are treated as scapegoats as both white workers and workers of color blame them for their problems in the workforce. Before World War II (1939–1945), for example, Japanese American farmers faced racist legislation that prevented them from owning land. During the war, they were put into concentration camps and lost nearly all their possessions.

More recently, many Korean-owned businesses in Los Angeles established a vibrant middlemen minority community in the 1970s and 1980s (Bonacich and Light 1988), only to have them targeted and burned down during the 1992 riots. Capitalism’s longevity is thus largely based on these racial and ethnic antagonisms.

This perspective, while theoretically and empirically rich, has generated concerns among some Marxist-oriented sociologists and historians. Bonacich, these scholars claim, mistakenly assumes that the working-class was primarily responsible for creating and sustaining racism. Michael Omi and Howard Winant (1994), in contrast, find Bonacich’s “economic determinism” and “class reductionism” troubling. Miles and Brown (2003), moreover, suggest that racism exists autonomously from capitalism, meaning that it predates capitalism and persists in socialist societies. It has also been claimed that class is no more important than gender, race, or sexuality, and that social movements and nation-states socially construct “race” around certain practices, projects, and discourses (Anderson and Collins 2006; Omi and Winant 1994). The fact that Omi and Winant’s “racial formation paradigm” became so influential in the 1980s and 1990s is extremely ironic because discussions about class—that supposedly “anachronistic” and “old-fashioned” concept—made a “comeback” as economic inequality rose in the United States and around the world during that same time period.

Globalization, or what some Marxists call imperialism, is largely responsible for this latter trend. Capitalism reproduces itself through imperialism, which generates poverty and misery within the “Third World,” leading to migration into developed countries like the United States. This fact, coupled with U.S. support for neoliberal economic policies and right-wing dictatorships, facilitated significant migration from Mexico and Central America in the 1980s and 1990s. These Latino migrants made up the backbone of the Los Angeles garment industry, which became the nation’s largest site for apparel production in the 1990s.

Los Angeles garment workers have endured “sweatshop” conditions, involving very long hours and extremely low pay. The “return of the sweatshop” resulted from the restructuring of the U.S. economy following the worldwide economic crisis of the 1970s. “Restructuring” involved cutting back social programs, attacking labor unions, and rolling back legal protections for workers. The resistance efforts of workers have not been very effective, however, because garment workers sometimes see their immediate employer, typically an Asian immigrant contractor, as their “enemy” (Bonacich and Appelbaum 2000). But the real power brokers in the garment industry are giant retailers and manufacturers like Wal-Mart and Nike, which are usually controlled by wealthy white men. Class conflict, therefore, is played out along racial lines. The middlemen minority group (Asian contractors) is blamed for labor’s woes, while capital goes largely unchallenged.

Bonacich and Appelbaum note that even when capital is challenged—such as when the U.S. garment workers union, UNITE, targeted Guess Inc. in the mid-1990s—it can simply shut down and move someplace else. The Guess campaign and many others inside and outside the United States were undermined by capital mobility in the 1990s. Because the garment industry is so mobile, better opportunities for labor organizing may lie within nonmobile sectors like the logistics industry. Bonacich, along with Jake B. Wilson, has been studying the possibility of organizing longshore, trucking, transportation, rail, and warehouse workers (mostly people of color), who could potentially bring global capitalism to a standstill if they refused to handle goods that came through the ports of Los Angeles and Long Beach.
These have been the hallmarks of Professor Bonacich’s distinguished career. She has not only interpreted the world, but, as Marx famously said, she has worked to change it for the better through her research, teaching, mentoring, and involvement with the labor and anti-sweatshop movements. Her provocative work on split labor markets, middlemen minorities, immigration, sweatshops, and global production has influenced numerous scholars and activists. Split labor market theory, for instance, is mentioned in most introductory sociology textbooks, while her studies on the Los Angeles garment and logistics industries have been invaluable for labor unions and community organizations. She is a true role model for progressive academics who wish to combine scholarship with activism.

BOOTSTRAP METHOD

The bootstrap method, introduced by Bradley Efron (1979, 1982), is a technique for making statistical inference. In the typical estimation scenario, one draws a sample \( Y = \{y_1, \ldots, y_n\} \) from an unknown distribution \( F \) and then computes an estimate \( \hat{\theta} = g(Y) \) of some parameter or quantity \( \theta \) that is of interest. If the distribution of \( (\hat{\theta} - \theta) \) were known, it would be straightforward to find values \( c_1, c_2 \) such that

\[
P(c_1 < \hat{\theta} - \theta < c_2) = 1 - \alpha
\]

for some small value of \( \alpha \), say 0.1 or 0.05. Rearranging terms inside the parentheses results in a confidence interval, \( \hat{\theta} - c_2 \leq \theta \leq \hat{\theta} - c_1 \), for the quantity \( \theta \). The distribution of \( (\hat{\theta} - \theta) \) is unknown in most situations, however. In some cases, the finite-sample distribution of \( (\hat{\theta} - \theta) \) can be approximated by the limiting distribution, but this may not work well in some cases.

The bootstrap method is based on the idea of replicating the estimation scenario described above by drawing \( B \) samples \( Y^* = \{y_{1*}, \ldots, y_{n*}\} \) from an estimate \( \hat{F} \) of \( F \) and computing estimates \( \hat{\theta}_b = g(Y^*_b) \), \( b = 1, \ldots, B \). Given the \( B \) values \( \hat{\theta}_b \) it is straightforward to find values \( c_1^*, c_2^* \) such that

\[
P(c_1^* < \hat{\theta} - \hat{\theta}_b < c_2^*) = 1 - \alpha
\]

by finding appropriate percentiles of the differences \((\hat{\theta}_b - \theta)\). Substituting the values \( c_1^*, c_2^* \) into (1) yields...
Rearranging terms inside the parentheses in (3) yields an estimated confidence interval

\[ P(c_1^* \leq \hat{\theta} - \theta \leq c_2^*) = 1 - \alpha. \]  

(3)

Here, confidence intervals have been estimated based on the differences \((\hat{\theta}_B - \bar{\theta})\), but other approaches may also be used (see Efron and Tibshirani [1993] for examples). The approximation in (2) is due to the fact that \( B \) must be finite, while the approximation in (3) is due to the fact that the original estimate \( \hat{\theta} \) is based on a finite sample of size \( n \); the first approximation improves as \( B \to \infty \), and the second approximation improves as \( n \to \infty \).

Variants of the bootstrap method also differ according to how the bootstrap samples \( Y' \) are constructed. In the naive bootstrap, \( Y' \) is constructed by drawing from the empirical distribution of the original data \( Y \). This approach “works” in the sense of yielding estimated confidence intervals with correct coverages whenever the limiting distribution of \( \hat{\theta} \) is normal, as proved by Enno Mammen (1992). However, the naive bootstrap often fails in other situations (see Bickel and Freedman [1981] for examples). In cases where data are bounded, constructing bootstrap samples by drawing from a smooth estimate of \( F \), rather than the empirical distribution function, often yields confidence intervals with correct coverages; this approach is called a smooth bootstrap. The smooth bootstrap has been used with data envelopment analysis (DEA) estimators to estimate confidence intervals for measures of technical efficiency (see Simar and Wilson [1998, 2000] for details).

The bootstrap method has been increasingly used as computers have become faster and cheaper. It is particularly useful in situations where limiting distributions involve unknown parameters that may be difficult to estimate, which is often the case with nonparametric estimators such as DEA. The method is also useful in situations where limiting normal distributions provide poor approximations to finite-sample distributions of estimators. By constructing bootstrap samples by drawing from either the empirical distribution or a smooth estimate of the distribution of the original data, the bootstrap method incorporates information about higher moments (e.g., skewness, kurtosis, etc.) that is ignored when limiting normal distributions are used to approximate finite sample distributions. This sometimes leads to bootstrap confidence interval estimates with better coverage properties than more conventional confidence interval estimates.

**BORDERLANDS**

**SEE** Borders.

**BORDERS**

All territorial entities have borders, defined as the area where one territory ends and another begins. Borders can be delineated along natural divisions such as mountain ranges or rivers or they can be artificially created. Once delineated, governments demarcate significant portions or all parts of a border with actual markings such as fences, posts, or border checkpoints. The majority of the world’s borders are agreed upon, but border disputes exist in all regions of the world. Because border disputes can escalate to armed conflict or war, governments pay significant attention to borders. For this reason, the study of borders is primarily a political issue, but also involves economic and cultural issues.

Politically, borders are most significant for states to signal where their sovereign power exists. Borders are important to states both in actual and symbolic terms. In actual terms, borders protect the state and its population...
from foreign intrusions and potential threats. Most states maintain strict border controls, mandating that foreigners apply for entry or check in with government officials at the borders. Borders are also often secured to prevent potential attacks from hostile neighboring states or individuals. In a few cases, states such as those in the European Union have demilitarized their borders and opened them to allow for the free flow of people, goods and services, and money, making state borders less relevant. In symbolic terms, borders act as clear indicators to neighboring states that they should not interfere in the governing of territory beyond the border. A key component of sovereignty is territorial control as delineated by a state’s borders.

A territorial dispute exists when one state challenges the recognized location of a border. Some of the best-known border disputes have been between India and Pakistan, Ethiopia and Eritrea, Israel and Lebanon, and China and Vietnam. States can resolve border disputes in a variety of ways. The challenging state can attempt to use armed force to move the location of the border, creating an armed conflict. The competing states can also work through bilateral or multilateral negotiations, mediation, arbitration, or adjudication through the World Court. Once a border dispute is settled, the competing states sign a treaty agreeing to the delineation and demarcation of the revised location of the border.

In economic terms, borders signify where a state’s economic control exists regarding its gross national product, standard of living, economic policies, currency use, and imports and exports. Borders act as checkpoints for the movement of workers, goods, and services, preventing the ease of sharing labor between states. Culturally, borders often separate distinct cultural groups, both in real terms and metaphorically. In most cases, crossing a border indicates a shift in language, religious practices, social practices, customs, traditions, and food. Borders can also divide one cultural group so that members of a group live in two or more states. In some cases, divided cultural groups seek to reunite through secession or irredentism, causing tension or armed conflict. Borders have both positive and negative connotations, depending on which side of the fence one is located.

**BORICUA**

The ethnic expression Boricua describes someone or something native to Boriken, Borique, Boriquén, Borinquent, Boriquí, or Boriquer—all variations of the Arawak name for the island that Christopher Columbus claimed for Spain in 1493 during his “discovery” of the Americas. While the Iberians later christened it Puerto Rico (Rich Port) in the mistaken belief that it was a veritable gold mine, in 1552 the chronicler Francisco López de Gómara referred to it as “San Juan del Boriqua.” Maintaining that the aboriginal population had died out, Spanish colonial authorities made only sporadic use of either Borinquen or Boricua during the next two centuries. Their tallies rarely took into account the undercounting of Tainos by colonists seeking to dodge taxes and import “sturdier” African captives, nor of Tainos who fled into the interior or were reclassified as mestizos. Although some 2,000 “indios” still existed in Puerto Rico at the start of the nineteenth century, Boricuas had undergone a significant ethnogenetic transformation since 1493 as a result of miscegenation with poor, persecuted whites and enslaved Africans who also fled to the mountainous interior.

Over time, a pluricultural population of rural mulatto-mestizo peasants known as *jibaros* emerged in Spanish colonial Puerto Rico. Characterized by a conscious rejection of Roman Catholic orthodoxy, forced labor, and Iberian cultural hegemony, they dwelled on the periphery of their colonial overseers where they evoked, celebrated, and perpetuated the original pre-Columbian names for the island and its aboriginal people. The *jibaros* embraced a libertarian ethos that appealed to anticolonial and anti-slavery causes. For instance, an independence conspiracy led by the German general Ducoudray Holstein in the early 1820s called for the establishment of a República Boricua. An 1853 novel by ardent abolationist and pro-independence militant Ramón Emeterio Betances was titled, *Les Deux Indiens. Episode de la Conquête de Borinquen.* Even the national anthem of Puerto Rico, “La Borinqueña,” a *danza* penned in the 1860s, retained the Antillean appellation. A vast number of modern-day rural barrios, neighborhoods, roads, urban communities, streets, and avenues across the island are called Borinquen. Countless literary, artistic, and musical productions make use of Borinquen and/or Boricua instead of their Spanish counterparts.

Puerto Rican separatists operating in the United States starting in the late 1860s, among them Betances,
BOSE, SUBHAS CHANDRA AND SARAT CHANDRA

Political leaders from Bengal involved in the Indian nationalist movement in the first half of the twentieth century, Sarat Chandra Bose (1889–1950) and Subhas Chandra Bose (1897–1945) were brothers from a successful high-caste family headed by their father, Janaki Nath Bose. The two brothers attended Presidency College, Calcutta, one of the leading colleges of British India.

Sarat Bose went to Great Britain and was called to the bar from Lincoln’s Inn and had a lucrative legal career before the Calcutta High Court for more than three decades. Meanwhile, his more impetuous and devoted younger brother was dismissed from college for involvement in an attack on a British professor who had insulted India. However, Subhas Bose continued his education at Scottish Churches College, graduated, and went on to secure a high position in the examination for the Indian Civil Service in 1920.

Preferring to work in the nationalist movement led by Mahatma Gandhi (1869–1948), Subhas Bose resigned from the civil service and joined the struggle against British rule in his home province of Bengal. In 1924 he became chief executive officer of the Calcutta Corporation (city government), but was arrested soon thereafter for suspicion of smuggling arms. He was imprisoned in Burma and released in 1927. Meanwhile, his activity drew his older brother into nationalist politics and Calcutta affairs.

After his release, Subhas Bose became an important leader of the younger, socialist-inclined nationalists in the Indian National Congress (INC), the main nationalist organization. Although he worked with the nonviolent Gandhian movement, he also had links to underground nationalists who committed acts of violence against their British rulers. In 1930 Subhas Bose was elected mayor of Calcutta and participated in Gandhi’s civil disobedience movement. Again arrested in 1932, Subhas Bose was released to go to Europe for medical treatment. Sarat Bose was also arrested and spent 1932 to 1935 in prison.

In the late 1930s Subhas Bose became president of the INC at Gandhi’s behest and his brother Sarat was leader of the opposition in the Bengal Legislative Assembly. A conflict with Gandhi led to Subhas Bose’s resignation from his INC leadership post in 1939 and then his suspension for disobeying INC strictures about demonstrations. Sarat Bose continued playing an important role in Bengal politics until December 1941. The opening of World War II (1939–1945) changed everything in India.
Believing that the British would never leave India peacefully, Subhas Bose departed India secretly in January 1941 and made his way to Germany, where he set up a propaganda center and organized a small force of Indians into the Indian Legion. He decided to cooperate with the enemies of the British Empire to help destroy it. Because his younger brother was working with the enemy, Sarat Bose was imprisoned from 1941 to 1945.

In 1943 Subhas Bose traveled to Southeast Asia and with Japanese help organized the provisional government of free India and reorganized the Indian National Army (INA) to oppose the British. The Japanese and the INA invaded India in 1944 but were defeated by the Allies. Subhas Bose died in a plane crash in Taiwan in August 1945 as the war ended. Members of the INA were tried for treason, convicted, but then released by the British. In death, Subhas Bose (called “Netaji” or revered leader) became more beloved than in life. Some even disputed that he had ever died in the plane crash.

Sarat Bose was briefly a cabinet minister in the interim government in 1946 and worked to prevent the partition of India as the British prepared to leave the country. After independence and partition in August 1947, Sarat Bose became an opponent and critic of the ruling Congress Party in India, but he died shortly thereafter in 1950.

BOSERUP, ESTER 1910–1999

Ester Boserup was born in Copenhagen in 1910 and graduated from the University of Copenhagen in 1935 in theoretical economics within a broad social science background. Her research work began with a decade at the United Nations and its agencies in the late 1940s; she spent the remainder of her career as a consultant and independent researcher. She died in 1999.

Boserup’s primary focus is the relationship between population growth and food supply. The English economist Thomas Robert Malthus (1766–1834) and his followers believed that food supply can only grow slowly and is the main factor governing the rate of population growth. Population growth is therefore seen as the result of previous changes in agricultural productivity. Boserup approaches the problem from the opposite direction. She sets out to demonstrate that the primary stimulus to agricultural productivity is population growth itself.

Boserup groups land use into five different types in order of increasing intensity. The first is forest-fallow, in which plots of land are cleared in the forest and planted for a year or two. The land is then left fallow for twenty to twenty-five years in order for the forest to regenerate. With bush-fallow, this period is only six to ten years, in which time the land is covered in bush and small trees. Short-fallow is a system in which the fallow period is one or two years, during which the land is invaded by wild grasses. With annual cropping, the land is left uncultivated for only several months between harvest and planting. Finally, multicropping occurs when the same plot of land bears two or more crops every year. But Boserup does not mean the land-use typology to be a classification scheme only; rather, it is meant to characterize the main stages of the evolution of agriculture from prehistoric times to the present.

Once “frequency of cropping” is used as a measure of intensification, theories of the development of agriculture can be directly linked with changes in local landscape, flora, and fauna. For example, as people shorten the fallow period, forests deteriorate and bushes take over the land. Further intensification will bring wild grasses. In this way, many forest and bush areas gradually became savannah as a result of the intensification of agriculture. These new grasslands provide food for cattle, horses, and other animals suitable for domestication.

Both the methods of cultivation and fertilization must become more labor intensive with the shortening of fallow. While such methods produce more crops per acre, they also require far more human labor to produce these yields—and the increase in yield is not commensurate with effort. The short-term effect of intensification, Boserup maintains, necessarily lowers output per man-hour. The investments in labor are so large that they are not likely to be made unless population increase makes them necessary. But there are “secondary effects” of the growth of population that lead to real economic growth in the long term. These secondary effects include a compulsion to work harder and more regularly, changing work habits that raise overall productivity, and the facilitation of urbanization, communication, education, the division of labor, and the further intensification of agriculture.
Yet another major contribution Boserup made to the literature on development was her book *Woman’s Role in Economic Development* (1970). In this book, Boserup made clear that gender is one of the main criteria for the division of labor in all societies; but, she argued, there is a great diversity in this division of labor between the sexes across societies. The primary factors that are related to the work and subsequent status of women are population density and the availability of land. This division of labor in farming systems carries over into nonfarm activities as well.

Boserup does not so much refute Malthus as round him out by providing a more complete picture of the multitude of relationships between population, agricultural production, and the environment. While Malthus focused upon the necessity to keep human numbers in line with the food that could be produced, Boserup focuses upon how the amount of food that can be produced is dependent upon human numbers. She demonstrates that agricultural production is quite responsive to increased labor. Malthus, on the other hand, also recognized that the production of food could be increased, but he asserted that such intensification could never equal natural population growth for long. Boserup did not dispute this; she did document the fact, however, that a growing population often stimulates an intensification of agricultural production. Malthus made similar assertions in his *Essay on the Principle of Population* (1798). For Malthus, the principle of population “keeps the inhabitants of the earth always fully up to the level of the means of subsistence; and is constantly acting upon man as a powerful stimulus, urging him to the further cultivation of the earth, and to enable it, consequently, to support a more extended population” (Malthus [1798] 2001, p. 281). Boserup’s main contribution is in clearly positing these relationships and empirically verifying them throughout the social evolutionary process. Her basic model had great influence on the social evolutionary theory of Mark Cohen, Marvin Harris, and Gerhard Lenski.

**BOURDIEU, PIERRE**

1930–2002

Pierre Bourdieu was one of the most prolific and influential social theorists of the second half of the twentieth century. Not only was his output astonishing, but his work has been cited continuously and approvingly by an array of scholars from many disciplines. His initial work intervened in sociology, but as his scholarship broadened, he sought to influence philosophy, anthropology, cultural criticism, psychology, gender studies, linguistics, economics, and finally, for the last two decades of his life, the political arena itself. He is well known for introducing a number of important sociological concepts that have since gained wide currency.

The son of a postal employee, Bourdieu spent his earliest years in a small town in southwestern France, speaking the provincial language, Gascon. At eleven he moved to a boarding school, and by sixteen he was attending the Lycée Louis-le-Grand in Paris. From there he gained entrance to the prestigious École Normale Supérieure. After this background at the top schools of the nation, Bourdieu became a teacher himself; but military service took him to Algeria (then still a colony of France), where he secured a teaching post.

His earliest study, *Sociologie de l’Algérie* (1958, translated as *The Algerians* in 1962), published in the midst of the war of independence in Algeria, established Bourdieu as an important and daring sociologist. In this first book, he divided the peoples of Algeria into four major ethnic categories and showed how colonization had impacted their lives, in effect causing what he called “the total disruption of society.” In this book’s core distinction between traditional and modern life, the former being swept aside by the latter, one can already see the seeds of Bourdieu’s major theoretical concerns with social domination and practice theory. His lifelong ethical commitment to the notions of autonomy, fairness, and equality also gained its first footing in this study.

After returning from his five-year stay in Algeria in 1960, Bourdieu taught at the Sorbonne and was later appointed director of studies at the École des Hautes Études en Sciences Sociales in 1964. In 1975 he launched his influential journal, *Actes de la recherche en sciences sociales* (Records of Research in the Social Sciences), and
by 1981 he had attained the prestigious chair of sociology at the Collège de France.

While still publishing influential articles and books on Algeria, he also became interested in social reproduction and began to look deeply into the French educational system and the culture of the Bearn, the part of France where he grew up. As he admitted in several interviews, his own dramatic social trajectory along these same paths contributed much to the sparks of insight that led to his most illuminating theories.

In his much-cited *Outline of a Theory of Practice* (1977), Bourdieu sets forth many of his central ideas, including *symbolic capital*, *doxa*, *habitus*, and *misrecognition*. His signal contribution in advancing these ideas was to overcome the limits of subjectivism and objectivism then current in much social thought, divided as it was between the phenomenological tradition and the structuralist one. As a major contributor to the emergent school of poststructuralism, Bourdieu continued to rely heavily on the central dichotomies and contradictions that he found prevailing throughout social life, but he attempted to return agency to the individual within these “objective” structures; this was masterfully displayed, for example, in his analysis of the gift in the *Outline*.

Bourdieu’s *Distinction: A Social Critique of the Judgement of Taste* (1984) remains as influential as the *Outline* (it was named one of the “books of the century” by the International Sociological Association); in it, he uses extensive empirical data to show that cultural preference is constituted by endless competition over scarce symbolic, cultural, and economic capital. *Distinction* also stands as strong testimony to Bourdieu’s commitment to inductive research methods.

In many ways, Bourdieu was a stalwart defender of the scientific heritage of the social sciences. He issued methodological statements concerning the best way to maintain an objectivist stance while undertaking necessarily subjectivist research, and his central belief in the process of misrecognition revealed that, for Bourdieu, the social world was clouded and distorted by the interests of specific powerful players. The task of sociology was then to unveil the actual reality lying underneath these strategies.

Late in life, Bourdieu joined with another French scholar, Loïc Wacquant, in applying these theories to the social world of scholarship itself. In a salvo titled “On the Cunning of Imperialist Reason” (1999), Bourdieu and Wacquant accused American social science of employing its financial and social clout in order to export American folk theories of race to the rest of the globe, much as he had documented the French state’s exportation of social categories to Algeria long ago. In this manner, the misrecognized American system of race was insidiously imposing itself abroad and was seen to be creating racial categories where perhaps none existed previously. John French, a scholar of Brazil, strongly rebuked Bourdieu and Wacquant, not least by pointing out that their argument rested upon an idealized French folk theory that imagines the creation of a social world devoid of all forms of prejudice. Further, the debate revealed a central weakness of the concept of misrecognition by showing that it is built upon the problematic idea that good scientists can gain access to a non-socially produced, and therefore “objective,” reality.

In this regard, Bourdieu can be seen as an heir to Auguste Comte (1798–1857) and Johann Fichte (1762–1814), for he strongly believed that a rationalist social science could liberate humankind from its current “objective conditions.” Bourdieu put this belief into practice consistently in the latter part of his life, as he became one of the more outspoken and articulate opponents of neoliberalism and globalization.

**BOURGEOIS MODE OF PRODUCTION**

**SEE** Capitalist Mode of Production.
**BOURGEOISIE**

In classical Marxian theory, *bourgeoisie* refers to the ruling class of capitalist society. Superseding the feudal aristocracy, its origins have been traced to a relatively early stage in capitalist development, when it was defined by ownership of the means of production. Since the 1800s the functions of management and ownership have become separated, however. As this has occurred, the explanatory value of the term *bourgeoisie* has become attenuated, particularly in discussions of advanced or late capitalism in the era of finance.

In French, *bourgeoisie* originally referred to the society of free men in towns, implying a citizen subject to civil law. The German political philosopher Karl Marx (1818–1883) and his collaborator, the German socialist Friedrich (also spelled Frederick)Engels (1820–1895), understood the bourgeoisie to have emerged from the class of “chartered burghers” in medieval towns, and in their works they trace the development of this class through several stages, from relative oppression under the feudal nobility, to militarized self-governing associations, to independent republics and taxable estates. They also linked the rise of this class to the simplification of class antagonism into a fundamentally binary opposition between the bourgeoisie and the proletariat. Marx never described the actual composition of the bourgeoisie as completely as he described the proletariat, and often the term appears to be interchangeable with *capitalist*.

The factors facilitating the rise of the bourgeoisie were both economic and geopolitical, and these two were related. In Marx's analysis, the drive to accumulation inherent in capitalism must be understood in terms of two kinds of capital, including constant capital (the value of the means of production) and variable capital (the value of labor power). Any expansion in total capital requires a growth in variable capital, which is generally achieved through the enhancement of technological means enabling the increased productivity of labor. A contradiction lies at the heart of this relation, however, for the variable portion of the capital grows more slowly than does the constant portion. This is overcome, says Marx, by increasing the scale of production; the larger the enterprise, the more capacity for accumulation it will have.

The process is, nonetheless, not linear. To begin with, the drive to accumulation generates competition among different capitalists. The result is a complex dialectic between accumulation and concentration, as well as centralization. In this environment, large-scale capital is not only advantaged in relation to smaller capital, because it can control more labor, but it grows at the expense of smaller capital. Such centralization is made possible by the credit system. Moreover, as the economist Rudolf Hilferding has argued, it is the merging of banking and industrial capital that permits and actualizes this centralizing dynamic—though not without countervailing pressures.

Through the credit system, the idle money that accumulates in the course of production is gathered together and made available for investment in production. Time is of the essence here, for the period during which money is not invested in production is, from the perspective of capital, lost. What the banks do, then, is permit enterprises to keep their own money in production, while still being able to draw on it for enhancement or expansion when opportunity arises. When assisted by banking institutions, the corporations no longer have to keep their money in reserve for such opportunities. There is, then, a phantomatic extension of the corporation through credit.

At the same time, other institutions, such as the stock market, permit the creation of joint-stock companies in which collectivities rather than individuals come to function as owners. This “special institution,” as Hilferding termed it, provides a market for “titles to interest, or fictitious capital” (1981, pp. 107–180). Money is transformed into productive capital through the stock market because the shareholders only expect a return on the yield of the company, and their sale of title does not lead to a withdrawal of money from the corporation's productive machinery.

In this sense, the shareholder is not an owner of the means of production. He is, rather, representative of a new kind of capitalist, a money capitalist, defined by Hilferding as one liberated from the status of industrial entrepreneur. Like the manager, his actions serve the interests of the company and hence of corporate capital, but only in an extremely mediated fashion. Accordingly, many thinkers, most notably Nicolas Poulantzas, argue for a reconceptualization of the bourgeoisie as a class defined not by ownership of the means of production but by the function of economic control. Others have disputed this and have preferred to see managers as special kinds of wage laborers.

With the rise of the stock market, and speculation more generally, the creation of value appears to become increasingly separated from the question of production. Initially, this market sought to attract large-scale capital, accumulated by members of a relatively conventional bourgeoisie. Other institutions, such as mutual funds, have extended this process however and, consequently, helped to disseminate the capitalist ideal even among those who are merely wage laborers. They represent a profound cultural transformation and may perhaps help explain the subversion of class consciousness in social milieus defined by financialization. Nonetheless, it is important to understand that industrial capital continues to play a crucial role even in financialized contexts, and
the vast majority of the world’s labor remains engaged within it, even though a disproportionate amount of value is produced in and by financial capital.

The forces that would ultimately lead to the political and social transformation of capitalism were, Hilferding thought, internal to capitalism itself. Other, liberal theorists agreed, though for different reasons. Adolf Berle, for example, saw the concentration and centralization of capital in the huge corporations of the United States in the mid-twentieth century as a direct product of joint stock organization. But while relying upon state regulation, which, for example, provides tax incentives for philanthropic giving, Berle argued that the new corporations themselves assumed a “quasi-political” role. He argued further that the greatest incentive to corporate growth and rationalization is the threat of competition from state enterprises. Corporate investment in local infrastructural development and education as well as international diplomacy carried out by corporate representatives constitutes, for Berle, the hallmark of a specifically American form of corporatist capitalism whose defining attribute is its antipathy to statism.

Berle’s conception of what might be termed, in an idiom coined by the French philosopher Michel Foucault, corporate “governmentality” may be contrasted to Marx’s original conception of the relationship between bourgeois political and economic form. Marx had argued that the bourgeoisie assumed economic predominance partly through its development of a political form capable of representing its interests, namely bourgeois democracy. Although a national entity, the bourgeois democratic state was nonetheless made possible only by the reordering of local economies in colonial territories—to produce markets for European goods and to permit the extraction of natural resources for processing in metropolitan centers or, later, to serve as export processing zones. Hilferding went so far as to argue that the inhibiting influences of cartelization and protectionism within European states could only be overcome by outward expansion, and hence that the development of European capital led inevitably to imperialism, a thesis shared in different ways by both the Russian Communist thinkers Nikolay Bukharin (1888–1938) and Vladimir Lenin (1870–1924).

Toward the end of the twentieth century, economic theorists began to observe a rupture in the relationship between nation-states and corporate capital, and a supercession of the bourgeois nation-state by regional trade bodies and economic consortia (such as the North American Free Trade Agreement, the European Union, and the G8) that, while backed by the governmental authority of nation-states, attempt to ensure that domestic protectionism, which might have been deployed by national capital, does not inhibit the expansion of capital, per se. As Hilferding anticipated, financial institutions have assumed an increasingly dominant role in such contexts, and access to credit has become a significant index of economic power for both corporations and individual persons. The development of a sphere of value-creation relatively unmoored from production, through currency trading, real estate speculation, and derivatives trading, suggests that the old bourgeoisie has not only been liberated from the function of industrial entrepreneur but that the money capitalist has become the new bearer of capital’s own self-interest.

BOURGEOISIE, PETTY

The term petty bourgeoisie originally referred to the class of people involved in small-scale commercial enterprises who owned their means of production. It included merchants and traders, and, in some cases, wealthier land-owning farmers. Thus conceived, this class partakes of the structures of private property on which capitalist society is grounded, but it does not own sufficient capital to reap the benefits of large-scale industrialization and workplace rationalization. Moreover, its members are not dependent upon the sale of their own labor-power. They occasionally employ others, although, unlike capitalists, they them-
selves must also work, and often do so alongside their employees, including family members.

The petty bourgeoisie has been assigned a particularly significant role in Marxian historiography by virtue of Karl Marx’s (1818–1883) claim that, during the failed revolution of 1848 in France, they transferred their allegiance from the proletariat to the bourgeoisie. In the mid-1840s, a period of famine and widespread discontent throughout Europe but especially in France, the petty bourgeoisie had fought alongside members of the urban proletariat and students to demand workers’ rights and liberal political reform. However, when this conflict began to assume anarchic dimensions, they joined with the bourgeoisie, the conservative peasantry, and residual feudal powers to support a counterrevolution whose outcome was the establishment of the Second Republic and a new era of European despotism.

By the late twentieth century, the term had receded from usage, and has been replaced in large measure by middle class. This has occurred at the same time that the term middle class has come to be dissociated from its original referent of the bourgeoisie. The reasons for this development, particularly in the United States, reveal much about both the nature of economic life in contemporary capitalist society and the ideology by which it is sustained. This ideology can be described as one that valorizes the middle class, that sees its expansion as the necessary condition of economic growth and democratization, and that links middle classness to upward mobility.

Significantly, this understanding rests on a slippage in the definition of the middle class from Marx’s time. Friedrich Engels (1820–1895) had warned against this possibility in a letter to Marx in 1852. There, he distinguished the middle class as that group between the nobility, which it had superseded, and the proletariat, which would ultimately displace it. In this sense, middle class meant transitional class for Engels, rather than simply the class of small business people and professional managers now typically associated with the term.

However, the question of transition has itself become problematic in economic history. The joint stock company, which Marx believed to be a mere stage in the development and transformation of capital, now dominates capitalist enterprise, and its professional managers (as well as their support service workers) now form the core of what is sometimes referred to as the “new petty bourgeoisie.”

Like the more classically conceived proletariat, these individuals are also employees of capitalist enterprises. However, they do not own the means of production in the sense that enables them to alienate it, and they are somewhat contradictorily positioned as the representatives of capitalist interests. Various theorists have tried to exclude this new form of the petty bourgeoisie from the categories of both the bourgeoisie and the working class, on the basis that they perform “unproductive” mental labor which is antithetical to the interests of the proletariat (Poulantzis 1975); that they do not own the means of production despite exercising the “function” of capital (Carchedi 1977); or, more generally, because older notions of property ownership no longer describe the ambiguous distribution of rights over property that define modern joint stock companies today (Olin Wright 1978). In each of these cases, the managerial classes are thought of as a problem for both theory and radical political organization. Allin Cottrell (1984) nonetheless suggests that the variability in forms of ownership, social roles, and ideological commitments that characterize the managerial classes in contemporary capitalist societies requires a new conception of class, and prohibits any predictive model identifying the new petty bourgeoisie with any particular political orientation.

The older model of the petty bourgeoisie nonetheless retains great ideological force in many neoliberal societies, where the idea of the self-employed businessperson who is free from the demand to sell his or her own labor continues to occupy a dominant position in popular representations of the middle classes. It is often associated with radical individualism, as well as the values of personal autonomy and rational decision making. Moreover, it is frequently imagined as the ideal form of immigrant assimilation—and serves as a counter-image to balance other immigrant economies, including those of short term contract labor in the agricultural or energy sectors, and the feminized economies of domestic and sexual labor.

BOWLBY, JOHN
1907–1990

John Mostyn Bowlby was a British child psychiatrist who developed attachment theory, which posited that poor relationships (attachments) to caregivers in early childhood are the primary cause of most childhood disorders. When first introduced in the 1940s, attachment theory was shunned by the psychoanalytic movement because it conflicted with some principles of psychoanalysis that were popular at the time. Attachment theory is now highly regarded as a well-established and well-researched explanation of childhood behavioral and emotional problems.

Born in 1907 to an upper-middle-class family in London, Bowlby was raised in traditional British fashion by nannies, until he was sent to boarding school at age seven. After his 1928 graduation from the medical college at the University of Cambridge, he volunteered at two homes serving “maladjusted and delinquent” children. While there, he began to investigate the early influences of the family on later childhood difficulties. To further develop his ideas on the impact of family relationships on the mental health of children, Bowlby returned to school to study child psychiatry, psychoanalysis, and psychotherapy.

At the British Psychoanalytic Institute, Bowlby trained with instructors who were among the most influential analysts of the time, including Melanie Klein (1882–1960). Although trained primarily in adult psychiatry, Bowlby returned to his work with the London Child Guidance Clinic in 1937.

In 1940 Bowlby wrote the first of several controversial papers demonstrating his divergence from contemporary psychoanalytic trends. Bowlby stated that psychoanalysts should study the “nature of the organism, the properties of the soil, and their interaction” (1940, p. 23) rather than the unconscious drives or urges that characterized the Freudian approach to understanding childhood behaviors and emotions. While at the London Clinic, Bowlby began systematic research using patient case histories to link symptoms to parental “deprivation and separation” (Bretherton 1992, p. 761).

After World War II (1939–1945), Bowlby headed the Children’s Department at the Tavistock Clinic and began studying homeless children and children separated from their parents by hospitalization. In 1952 Bowlby and colleague James Robertson (1911–1988) filmed the documentary A Two-Year-Old Goes to Hospital, which alarmed clinicians regarding the impact of maternal separation, and influenced hospitals to change strict visitation policies.

In 1957 Bowlby presented the first formal statement of his theory that the mother-child attachment has an ethological-evolutionary foundation—that is, children, like the young of most animals, have innate behaviors promoting contact with the parent to enhance survival. Bowlby concluded that a child’s survival is more likely when the child is emotionally connected and in proximity to the mother. Bowlby eventually split completely from the Kleinian psychoanalytic school and established a research unit focused on mother-child separation, continuing his work with influential researchers, including Mary Ainsworth (1913–1999). Ainsworth’s research on the normative child-mother relationship across various cultures complemented Bowlby’s research. Ainsworth’s findings supported Bowlby’s theory of the importance of early parental relationships on the behavioral and emotional well-being of children.

Bowlby continued to develop attachment theory, and spent the last decades of his life, until his death in 1990, refining the clinical application of the theory.

BRACERO PROGRAM

In August 1942, more than ten thousand men converged on Mexico City. They were answering the government's call to combat fascism by signing up to do agricultural work in the United States. Although initiated as a temporary measure to alleviate a tightening U.S. labor market brought on by World War II, the Mexican–U.S. Program of the Loan of Laborers lasted for 22 years and awarded more than 4.5 million work contracts to nearly two million Mexican men. Competition for contracts also stimulated undocumented migration of at least that many. Many Mexican men (women could not participate) benefited economically from this regulated migration, but the biggest beneficiary of the Bracero Program, the unofficial name for the series of binational agreements, were large growers. The availability of thousands of desperate braceros, as the migrants were called, generated massive corruption in both countries, acted as a downward push on farm wages, undercut unionization efforts, and enabled growers to delay mechanization until it was cost-effective.

Soon after entering World War II, the U.S. government approached Mexico about the possibility of bringing laborers north. Most important to Mexico was that the U.S. government, not individual growers, be responsible for men migrating under the program, and that both governments monitor the proper functioning of the program and investigate abuses. For all but a brief interlude (1948–1951) did this condition stand. Complaints multiplied during this interlude, and the condition was reinstated with the start of the Korean War, when Mexico’s bargaining hand was strengthened because of a contraction in the U.S. labor market due to the war. Bracero agreements also contained wage guarantees (braceros were to be paid the area’s prevailing wage for the crop picked) and requirements for sanitary housing, access to medical care, and a minimum of weeks for which they would be paid, regardless of weather conditions, making braceros’ protections far stronger than those extended to U.S. domestic farm workers. Although the agreement stipulated that growers prove they had attempted to recruit U.S. workers before their request for Mexican laborers be granted, in practice this requirement was waived or ignored. Generally growers, relying on long relationships with local government officials, had only to say they could find no U.S. laborers to work for the advertised wage and their request for braceros would be granted. Over time these practices depressed wages and undermined unionization.

The United States always controlled the maximum number of bracero spots offered, and Mexico could allocate these spots (or fewer ones) according to domestic needs. Thus, Mexico theoretically retained the right to decide where braceros worked. It acted on this right initially when it refused to send men to Texas, citing a history of discrimination against Mexican citizens and Mexican Americans. In response, in 1943 Coke R. Stevenson, the governor of Texas from 1941 to 1947, instituted the Good Neighbor Commission to investigate the problem. Convinced that Texas was taking steps to address the problem or merely recognizing that undocumented migrants were crossing into the United States anyway, Mexico consented and by 1947 state-sanctioned braceros were heading to that state. Also negotiated by the two countries was the location of reception centers where the final bracero selection would occur. Mexico repeatedly pushed to place centers a great distance from the United States’ preferred locations at the border. Mexico also sought to reduce costs—Mexico paid men’s transportation and board to reception centers, after which the United States took over—and to control the outflow of migrants to prevent its own farm-labor shortage in northern Mexico, where workers were poorly paid and scarce. As reception centers moved closer to the border, undocumented migration increased. This move also drew men away from less well-paid farm labor in northern Mexico and aroused the ire of these large landholders. Initially the binational agreement also contained a provision that 10 percent of workers’ wages be put in escrow until the men returned. Mexico fought hard for this provision, in force between 1942 and 1948, as it wanted to guarantee that, in contrast to earlier migrations, the men would return home with funds that could be used to purchase tractors and other equipment. While Mexico was heavily invested in this provision, few workers knew of it, and most have yet to recoup these funds.

With alarmist discussion of a labor shortage, growers pressured the U.S. government to replicate the informal contract system that had prevailed during World War I, when labor agents recruiting in Mexico promised workers wages and living conditions that were too often unmet. The United States recognized, however, that Mexico would not agree to any program of regulated migration without certain conditions. Furthermore, the United States was not in a position to ignore conditions sought by Mexico, for much had changed since the earlier informal program. Not only did the United States government initiate the formal exchange of workers, but President Franklin Roosevelt (in office 1933–1945) had entered office determined to establish better relations with Latin America. In contrast to earlier doctrines, his Good Neighbor Policy emphasized cooperation and guaranteed the sanctity of each sovereign American nation. As well, the Mexican president, Lázaro Cárdenas (in office 1934–1940), had, in a show of national sovereignty, nationalized oil fields in 1938, many of which had been owned by U.S. companies. Although Cárdenas had
offered compensation according to the value companies listed on earlier tax rolls, the companies balked, saying that nationalized fields were worth more. Thus, in exchange for the Bracero Program and a recognition of Mexico’s sovereignty, the United States had not much earlier settled the compensation issue and conceded to some of Mexico’s demands. Over the course of the program, Mexico lost its leverage because its economy could not offer enough jobs, leading many men to migrate.

**AFTER THE BRACERO PROGRAM**

In the forty-plus years since the end of the Bracero Program, there have been numerous calls to bring it back in various forms. The most recent was President George W. Bush’s push to institute a guest-worker program similar to the Bracero program. An idea proposed during his 2000 campaign for president, it was put on hold immediately after September 11, 2001, then resurfaced in 2003. By then, his expanded proposal added a post-9/11 heavy dose of border security (including a physical and virtual fence), increased enforcement of laws already on the books, and the removal of all persons in the country without the proper documentation in exchange for his guest worker program; it was also part of a larger package of changes to immigration laws.

President Bush’s revised proposal garnered attacks from all sides. Citing downward pressure on workers’ wages and fearing the cultural impact of largely poor immigrants of color, the anti-immigration faction countered the Bush proposal by demanding that only the removal and enhanced-security conditions be instituted. This anti-immigration position is best exemplified by the Minutemen Civil Defense Corps and Congressman Jim Sensenbrenner of Wisconsin. The Minutemen, an armed volunteer force and a visible symbol of a growing nativist sentiment operating largely in border states, have taken it upon themselves to secure U.S. borders that they see the federal government leaving unprotected. Sensenbrenner spotlighted a focus on security with a bill called the Border Protection, Anti-terrorism, and Illegal Immigration Control Act of 2005. This legislation, which passed the House by a vote of 239 to 182, would have made it a felony for anyone to “assist” an undocumented person to “remain in the United States.” Although the bill stalled in the Senate, it generated a strong reaction, not only from pro-immigration groups, but from the immigrants themselves. On May 1, 2006, hundreds of thousands of immigrant protesters took to the streets in Chicago, Los Angeles, and other parts of the country in reaction to Sensenbrenner’s restrictive legislation; they demanded a comprehensive reform package that included a path to legal residency and citizenship. This immigration debate also heightened simmering tensions between Latinos and African Americans. Often pitted against Latinos and recent immigrants for low-wage jobs and shrinking economic resources more generally, many African Americans see themselves ever more on the losing end of a direct competition with Latinos and immigrants.

Immigrants again turned out across the United States for peaceful May Day 2007 marches as federal officials increased their investigations of job sites known or thought to cater to immigrants. These raids have brought quick arrests of undocumented workers. In the aftermath, children—often United States citizens—have been separated from undocumented parents and wives from husbands, sending reverberations through immigrant communities. In 2007 another immigration bill, the Security through Regularized Immigration and a Vibrant Economy Act of 2007 (or STRIVE Act), was introduced in Congress. Although it was not guaranteed passage in the Democrat-controlled Congress, this compromise between pro- and anti-immigration factions has sought to combine heightened border security and a Bracero Program–like guest-worker program with a real path to citizenship for the estimated 12 million undocumented persons living in the United States.

**BRAHMINS**

The word *Brahmin* appeared for the first time in Purush-Sukta, a section of the Rig Veda. The Purush-Sukta described the divine origin of human beings into the four social groups, or castes, that comprise Hindu society: Brahmin, Kshatriya, Vaishya, and Sudra. According to the Purush-Sukta, God Brahma gave birth to the divinities associated with each caste: Brahmin was born from the mouth, Kshatriya from the arms, Vaishya from the thighs, and Sudra from the calves of Brahma. Later on this concept of the divine origin of Brahmins and other castes was repeated in numerous religious texts, including the Manusmriti, the famous Hindu religious compendium of customary laws.

The Manusmriti codifies the Hindu social order—that is, the caste system. The caste system assigns rights to each of the four castes. These civil, cultural, and economic rights are divided in an unequal manner; however, Brahmin are placed at the top of the hierarchy of castes and given special privileges over the other castes, while basic rights are denied to other castes.

The Manusmriti makes it clear that Brahmin is the best of all creations on earth. Manu prescribed six main deeds for Brahmins: learning, teaching, performing *yajña*, getting *yajña* performed, giving donations, and taking donations. Kshatriyas were assigned the duty of war and defense, Vaishyas were directed to conduct business, and Sudras were enjoined to serve the three other castes.

The Brahmin was treated as the supreme creation based on the concept of purity, whereas other castes, especially the Sudras, were declared impure and hence inferior. This social construct was spread through a variety of subsequent religious texts, such as the Purānas. The mythical concepts underlying caste divisions became so powerfully resonant that even in the early twenty-first century some people carry the notion of the supremacy of Brahmins due to their blind faith in the Purānas.

The concept of Brahmin emerged in ancient India. References to the cultural and religious practices of early Brahmins reveal that they were basically a ritualistic group following a variety of primitive faiths. They invented numerous religious rituals around their philosophy of *yajña* (a religious ritual to satisfy the god). In the initial stage of their development, *yajñās* were associated with the sacrificing of animals and a few other rituals. They also became the source of earnings for the Brahmins through the religious concept of *daan-dakshina* (donation). Over time rituals became associated with more and more aspects of social and cultural life, as Brahmins began to prescribe rituals for every social and individual event, from birth to death. This development made the Brahmin community into a priesthood that also became divine. On the basis of this priesthood, the Brahmins claimed to be mediators between God and humans. Such ideas created the belief that God could be pleased only through Brahmins. Even kings became subservient to Brahmins. In this context it is interesting to note that Brahmins did not assign the office of king to themselves. They believed that kings would never go to heaven, because they have to engage in sinful activity to run the state. For this reason Brahmins chose Kshatriya, the next in the caste hierarchy after them, to become kings. At the same time Brahmins exerted indirect control over kings by acting as their advisers or prime ministers. Through this system, Brahminism became the rule of law not only in terms of religious practice but also in the day-to-day affairs of the state and society.

The divinity attributed to Brahmins and the caste system created huge inequities in society, such as the denial of certain basic rights to other castes and extreme forms of deprivation, particularly for the low-caste Sudras (the former untouchables). In reaction to these circumstances, Gautama Buddha challenged the Brahmin claim to a divinely based supremacy over other people and castes. According to Buddha, no one was born a Brahmin or a Sudra and anyone could become Brahmin or Sudra through his or her actions. He also challenged the infallibility of Vedas that had been declared divine by Brahmins. Buddha propounded the principle of social equality and argued that Brahmin, Kshatriya, Vaishya, and Sudra were all born similarly from the same part of the body as a result of biological union between man and woman. He also denied the existence of God and the soul.

Buddha’s teachings spread among all levels of the Indian population, which ultimately resulted in the rapid deterioration of the Brahminical order and the supremacy of Brahmins. There was, however, a revival of Vedic rituals in the last quarter of the ninth century associated with
Adi Shankarcharaya. This led to a corresponding decline in the influence of Buddhism. As Brahminism reemerged, the caste system became more rigidly based on an extreme form of untouchability. B. R. Ambedkar has described this victory of Brahminism over Buddhism as a cultural counterrevolution.

In the early twenty-first century the Indian constitution provides for equal individual rights and does not recognize distinctions based on the caste system and the traditional superiority of Brahmins. However, the residual consequences and effects of caste traditions are still felt in some cultural, social, and religious spheres if not all.

**BRAIN DRAIN**

Approximately 3 percent of the world’s population were immigrants in 2000 (International Organization for Migration [IOM] 2005). Within this group was a significant proportion of highly skilled and educated individuals who left their country of birth and settled elsewhere. This process is referred to as the *brain drain* because the sending countries in many instances lose a significant number of their most highly skilled people.

The economists’ approaches to discussing the brain drain were laid out in the early 1970s in a series of articles coauthored by Jagdish Bhagwati (1973, 1974, 1975, 1976). Although he was not the first economist to address the brain drain (see for example Grubel and Scott 1966, Johnson 1967, and Berry and Soligo 1969), Bhagwati and his coauthors were the first to address it systematically at a theoretical, empirical, and policy level. And many of the issues raised in these articles have become staples of the debate surrounding the phenomenon of the brain drain.

Although worldwide estimates of the proportion of immigrants who contribute to brain drain are not available, reliable estimates of immigrants and education status in Organization for Economic Cooperation and Development (OECD) countries are available. While highly skilled immigrants do immigrate to other countries, these OECD countries represent a significant destination. These estimates report that approximately 35 percent of immigrants over twenty-five years of age to OECD countries had a tertiary education, while only 11 percent of the worldwide labor force had the equivalent education (Docquier and Marfouk 2006). This means that on average those who emigrated were more highly educated than the population they left. In most instances the sending countries tend to be developing countries, which have lower rates of highly skilled workers in the population, while the receiving countries are developed countries. This occurs because most of this type of emigration is driven by the wage and opportunity differentials between countries and the preference given to the immigration of skilled labor by developed countries.

The magnitude of this phenomenon increased during the 1990s, and all evidence suggests a continuation of this trend (Docquier and Marfouk 2006). This is cause for worry for policymakers in developing countries, as they lose significant parts of their most educated individuals. For example, while individuals with tertiary degrees make up only 3 percent of the sub-Saharan African population, 43 percent of the emigrants have this level of education. Other regions face a similar problem. According to the World Bank in 2005, the numbers for tertiary educated individuals and emigrants with tertiary degrees are 6 and 47 percent respectively for Asia and 9 and 39 percent for the island nations of the Caribbean. These are not only significant proportions of the emigrants but can also be very large proportions of the stock of educated individuals within the country. For example, most Caribbean nations lose between 61 and 89 percent of their tertiary educated individuals to emigration, while numerous African countries lose over 30 percent (Docquier and Marfouk 2006).

While there are numerous concerns for sending countries, and often these may differ by country, three main concerns have been identified. The first is that these countries lose individuals who are important in the delivery of crucial public services such as health and education. Compounding this loss is that in these areas the sending countries do not have sufficient personnel. The second concern is that the individuals lost are among those most capable of contributing to the dialogue for both progressive political and socioeconomic change in the country. The third concern is that in most instances the significant cost of training these individuals has been primarily borne by the public sector and is now not recoverable in taxes these individuals would have paid and services they would have provided to the community (IOM 2005; Ozden and Schiff 2006). In contrast, receiving nations gain by filling in gaps in skilled personnel at a lower cost than they would have otherwise, and gaining in the different knowledge and insights that the immigrants bring. For example it has been estimated that a reduction in visas for graduate students and skilled immigrants to the United States...
would result in a reduction in both patent and grant applications (Chellaraj, Maskus, and Mattoo 2006).

The concern with brain drain has also resulted in the discussion of two related phenomena, brain gain and brain waste. Brain gain is the idea that because emigration raises the rate of return of education in the sending country, more investment might take place in education and could possibly lead to a net gain in educated personnel. This idea was formalized in the literature by Bhagwati and Hamada (1974). The most recent and comprehensive study, however, finds that the gains are small and do not replace the loss due to brain drain (Ozden 2006). Brain waste is a concern, raising the question of whether the receiving countries are efficiently using the skilled emigrants they receive. From the data available it appears that a large number of skilled immigrants to OECD countries often end up in jobs for which they are significantly overqualified. This can be the result of language or cultural barriers or lack of understanding of how to interpret qualifications from different educational institutions.

The brain drain has evaded easy policy prescription because successful policy that maintains an individual’s right to emigrate and recognizes the society’s loss from this emigration would require the collaboration of both receiving and sending nations. One of the more interesting and thought-provoking proposals addressing a number of the concerns raised by brain drain is a “brain tax” initially proposed by Bhagwati and Hamada (1974). The proposed tax was to be imposed on the émigrés and the funds collected administered by an international organization such as the United Nations Development Programme (UNDP) for development in less industrialized countries. The strength of this proposal was that it did not interfere with an individual’s right to migrate, but by taxing the individual it recovered some of the cost and positive externalities that the sending country had lost. It also marginally reduced the incentive to migrate by reducing the post-tax income of émigrés.

**BRAZELTON, T. BERRY**

1918–

In his roles as researcher, clinician, and advocate for parents, T. Berry Brazelton has been one of the formative influences on pediatrics in the United States for over fifty years. For much of the earlier part of the twentieth century, it was assumed that the newborn infant was a “blank slate,” operating at a brain-stem level, and the care of the newborn seemed to reflect this assumption. It can be
argued that one of the most important advances in the study and treatment of the newborn infant was the development and publication of the Neonatal Behavioral Assessment Scale (NBAS) by Brazelton and his colleagues in 1973. Unlike the classic neurological scales, which were designed to identify abnormalities in newborn functioning, the NBAS examines the competencies of the newborn infant while at the same time identifying areas of concern. It has been used in hundreds of research studies to assess the effects of a wide range of prenatal and perinatal influences on newborn behavior, including prematurity and low birthweight and prenatal substance abuse. From the time it was first published, the NBAS has been used to document cultural variation in newborn behavior across a wide range of cultures. In recent years, it has also been successfully used as a method of helping parents understand and relate to their infants.

Critics acknowledge that whereas the NBAS provides the most comprehensive description of the newborn’s current level of neurobehavioral functioning, and although a number of studies have reported a relationship between patterns of change in newborn behavior and future parent-child relations and developmental outcome, the NBAS’s predictive validity has not been convincingly established. Moreover, although many population studies have been conducted with the NBAS, it has never been standardized. Because of its emphasis on “examiner flexibility” and the importance of eliciting the infant’s “best performance,” the scale does not have a standard order of item administration and thus is judged by some researchers to lack the objectivity required by the classic psychometric assessment tradition. Brazelton and his colleagues maintain that careful training of examiners to the 90 percent inter-rater agreement level ensures the reliability of the results across settings.

Brazelton was born in Waco, Texas, on May 10, 1918, and graduated from Princeton in 1940. In 1943 he graduated from the Columbia University College of Physicians and Surgeons in New York City, where he accepted a medical internship. In 1945 he moved to Boston to serve his medical residency at Massachusetts General Hospital, before undertaking pediatric training at Children’s Hospital. His interest in child development led to training in child psychiatry at Massachusetts General Hospital and the James Jackson Putnam Children’s Center. With Professor Jerome Bruner, he was a Fellow at the Center for Cognitive Studies at Harvard University. The process of integrating his dual interests—primary care pediatrics and child psychiatry—culminated in 1972, when he established the Child Development Unit, a pediatriic training and research center at Children’s Hospital in Boston.

Like Benjamin Spock, to whom he has been compared, Brazelton has written books for parents that have influenced the beliefs and practices of parents everywhere. What characterizes Brazelton’s writings for parents is his focus on the nature of individual differences in behavior. Indeed, in the preface to Brazelton’s classic book Infants and Mothers, Jerome Bruner remarks, “What delights me most is Dr. Brazelton’s unflagging sense of human individuality.” Brazelton has published many other books for parents, including the Touchpoints and Brazelton Way books, and his work also includes the development of a fourth edition of the Neonatal Behavioral Assessment Scale with his colleague J. Kevin Nugent.

Brazelton is a professor emeritus of clinical pediatrics at Harvard Medical School and a professor of psychiatry and human development at Brown University. In 1995 Harvard University Medical School established the T. Berry Brazelton Chair in Pediatrics. Brazelton is founder of the Brazelton Touchpoints Center at Children’s Hospital, Boston. Established in 1993, Touchpoints is a preventative outreach program that trains professionals to better serve families of infants and toddlers.

BREZHNEV, LEONID
1906–1982
Leonid Brezhnev, leader of the Soviet Union from 1964 until his death in November 1982, was at the Soviet helm longer than anyone besides Joseph Stalin (1879–1953). Brezhnev grew up in Ukraine in an industrial working-
BRIBERY

In the strictest sense, bribery is defined as the giving of money or other valuables to public officials in exchange for that official not performing his or her required duties. For example, traffic police may be paid to overlook a traffic violation, or a judge to render a decision favorable to the briber. The concept of bribery often is used outside the context of government officials to include any instance of a person disregarding the obligations of his or her position in return for a payment; for example, a salesperson may pay the purchasing manager at a client firm to continue to order their goods. A useful working definition is given by Harvey James (2002): “any payment made to an agent is a bribe if the agent retains the payment” (p. 199). A payment made to a government official that stays with that official and is not deposited into government coffers is considered a bribe.

As is often the case in economics, James’s definition does not distinguish between bribery and extortion. Extortion refers to a situation in which an agent demands payment for a good or service that the payee has a right to have without any payment; in contrast, in bribery the agent demands payment for an extra benefit. Although there may be philosophical, moral, or ethical differences between the two terms, for economists they often fall under the same category, largely because of the similar

class family (his father worked in a steel plant). Not intellectually inclined, Brezhnev was a hard worker, a good organizer, and a decent student; moreover, he showed early signs of leadership and political ambition, quickly joining the Komsomol (communist youth group) and the Communist Party. Professionally, Brezhnev trained in both industrial and agricultural sectors. He worked in factories, certified as a land surveyor (1927), and received an engineering degree (1935), all while demonstrating leadership within his trade union and party organizations.

In 1936 in Ukraine, Brezhnev’s political career began, oddly thanks to Stalin’s “Great Terror,” which left high-ranking posts empty, allowing eager beginners like Brezhnev to advance quickly. By 1941 he had achieved the post of regional party secretary for defense industries and, crucially, made a lasting, good impression on Nikita Khrushchev (1894–1971), Ukrainian first secretary. During World War II (1939–1945), Brezhnev was assigned to the political administration of the Red Army. Though political administration was physically safer than other wartime assignments, Brezhnev later tended to exaggerate his heroic war performance, heaping an absurd number of medals on himself.

In 1950 Brezhnev began his ascent to the highest echelons of Soviet power when he was named first secretary of Moldova, charged with “Sovietizing” it. Two years later Stalin promoted Brezhnev to candidate member of the Presidium (Politburo), possibly to replace another lieutenant scheduled for removal by purge. Despite Stalin’s death in 1953, Brezhnev lost little political momentum, thanks to his Ukrainian connections to the new leader, Nikita Khrushchev. Khrushchev named him first secretary of Kazakhstan in 1955 in charge of the “Virgin Lands” scheme, and elevated him to full membership of the Presidium in 1957. By 1963 Brezhnev had become a secretary of the Central Committee, controlling daily party organization. From that powerful position, Brezhnev helped plan and execute Khrushchev’s overthrow in 1964, condemning Khrushchev’s impulsiveness and excessive power. Brezhnev then became one of three leaders, until he consolidated his paramount position by the mid-1970s. From then on, Brezhnev was clearly the most authoritative figure within a collective leadership.

Those eighteen years—the Brezhnev era—saw the Soviet Union rise to become one of the two global superpowers dominating the world. Living standards increased, while classes of modern, educated professionals expanded. There were no terrors, catastrophes, or major conflicts; life was stable for two decades. Accordingly, when Russians are asked to assess the best time to have lived in their country in the twentieth century, the Brezhnev era usually comes out on top. Yet, Brezhnev’s regime was a one-party dictatorship with no regard for human rights. It ruled through security police and censorship, and kept Eastern European nations in captivity. It brutally crushed the 1968 reform movement in Czechoslovakia, and invaded Afghanistan in 1979. The time of stability was also an era of stagnation and economic and social rot. Brezhnev’s collective leadership style led to extreme bureaucratic inertia, a government of enervated gerontocracy. When Brezhnev died, Yuri Andropov (1914–1984) inherited a superpower in deep decline. Though he made initial stabs at correcting those problems, Andropov’s protégé, Mikhail Gorbachev, would go further than anyone ever imagined.

The effects of these types of payments in competitive situations. If all of a firm’s competitors offer to bribe a government official to speed up the delivery of a required permit, then that firm must also pay the bribe in order to avoid falling behind the competition. Here the distinction between bribery and extortion is blurred.

Andrei Shleifer and Robert Vishny (1993) suggest that bribery harms firms more than an equivalent tax because of the secrecy associated with bribery. Government officials may encourage firms to produce goods or invest in sectors that are more easily subject to bribery. The effort to create bribe opportunities can make economies more inefficient. Paolo Mauro (1995) finds that countries with higher levels of corruption have lower investment and lower economic growth. At the micro-level, Simon Johnson, John McMillan, and Christopher Woodruff (2002) find that firms that are faced with paying bribes reinvest less of their profits back into their business. Bribery can cause firms to make inefficient decisions that can interfere with the overall growth of an economy.

International agencies such as Transparency International and the World Bank have focused international attention on the problem of bribery. Both publish country rankings based on perceived levels of corruption and bribery. Developing countries usually occupy the lower rungs of these rankings. These rankings, along with the evidence on the correlation between low growth and corruption, have made bribery a key issue in economic development. Although bribery is conceptualized as primarily an interaction between two individuals, a bribe-payer and a bribe-taker, it has far-reaching effects for firms and entire economies.

**BRIMMER, ANDREW**

1926–

Andrew Felton Brimmer, born in Louisiana in 1926 to sharecropping parents, became one of America’s premier public economists, serving as a member of the Board of Governors of the Federal Reserve System from 1966 to 1974 and as chairman of the Financial Control Board of the District of Columbia in 1996. He also founded and manages Brimmer and Associates, a private consulting company with many corporate clients since 1977.

In 1944 the young Brimmer moved to the state of Washington and worked as an electrician’s helper in the shipyards before joining the U.S. Army for two years. He later earned his BA (1950) and MA (1951) degrees in economics from the University of Washington. After a year of scholarly work in India supported by a Fulbright grant, he completed his PhD in economics in 1957 at Harvard University. Following a second Fulbright grant in 1958 that allowed him to help establish the Central Bank of Sudan, he served for five years as an economist at the Federal Reserve Bank of New York.

In 1963 President John F. Kennedy (1917–1963) appointed Brimmer to the post of deputy assistant secretary for economic affairs in the U.S. Department of Commerce. In this position, he authored an influential study documenting the effects of racial discrimination in public accommodations on interstate commerce, thus providing the constitutional justification for federal regulation of activities that otherwise might have been considered purely local matters to be left to the states. Brimmer summarized his contribution by noting that:

> What I did was to design an economic model which enabled me to examine the differential impact of segregation and discrimination on African Americans—from the point of view of travel, entertainment, consumer expenditure patterns, and the level of money income…. I was able to do computer simulations that tracked travel along three separate routes from Washington, D.C., … to Miami, Florida, … New Orleans, and … Chicago. The net result was that we were able to demonstrate that African Americans had to travel about twice as far and roughly twice as long as white Americans. This violated the Guidelines of the National Safety Council.

Once the Public Accommodations Section of the Civil Rights Bill became law in the summer of 1964, it was challenged by the defenders of segregation. The case quickly got to the U.S. Supreme Court, which unanimously upheld its constitutionality. The Court based its decision substantially on the testimony I prepared. (U.S. Supreme Court 1964; Brimmer 2006)
Brimmer, Andrew

Brimmer has returned frequently to issues of black economic progress, arguing strenuously for more black entrepreneurship, increased adoption of the corporate mode of organization (Brimmer 1973), strong educational achievement (Horatio Alger Association 1974), and careful attention to personal finances. He has simultaneously noted that the economic costs of unequal treatment accorded African Americans has significantly hampered access to higher-paying jobs and slowed the rate of black entry to managerial professions. Noting the national interest in ending unequal treatment, he argued that such discrimination deprived the U.S. economy of $215 billion in 1991, roughly 3.8 percent of GDP (Brimmer 1995).

In 1966 President Lyndon B. Johnson (1908–1973) appointed Brimmer to a fourteen-year term with the Federal Reserve Board of Governors (of which he served eight). He was the first African American to serve in this elite position. Recognizing Brimmer’s objectivity and analytical skills, President Johnson declared:

I do not expect Dr. Brimmer to be an easy-money man or a tight-money man…. I expect Dr. Brimmer to be a right-money man, one who, I believe, will carefully and cautiously and intelligently evaluate the Nation’s needs and the needs of all of its people, and recommend the policies which his conscience and his judgment tells him will best serve the national interest. (Johnson 1966)

Brimmer returned to public service in 1996. Willing to grapple with the daunting budgetary crisis of the nation’s capital, Brimmer accepted President Bill Clinton’s appointment to serve as chairman of the District of Columbia Financial Responsibility and Management Assistance Authority (the Control Board) in 1996. The Control Board was given sweeping authority over nine major city departments, including public works, health, education, and welfare. The Control Board met with resistance from some sectors of the District, including from those who resented the loss of the limited sovereignty that the District had obtained in 1973 and from public sector trade unions that objected to the fiscal austerity that was the federal mandate given to the Control Board.

As chairman of the Control Board, Brimmer was vested with a wide range of powers to deal with the fiscal deficits that the city had incurred. It was a contentious period. For instance, during his tenure, Brimmer sought as a top priority to improve the D.C. school system, which was in shambles (District of Columbia Financial Responsibility and Management Assistance Authority 1996). The Control Board took the institutional step of transferring authority from the Board of Education to an Emergency Transitional Education Board of Trustees that it had created. The U.S. Court of Appeals for the District of Columbia Circuit found that the Control Board could not legally do this, modifying Brimmer’s efforts at educational reform. Brimmer’s critics were harsh on both his management style and his policies. One even argued that “Brimmer’s imperiousness runs up and down the organization: never retreat, never admit you were wrong, and never, ever say you’re sorry. Brimmer believes that he and his cohorts are on a mission and that he has a sovereign right to run over all objections” (Stabile et al. 1998). During this period, controversies were legion. For instance, in 1997 Brimmer was forced by outraged District residents, Control Board members, and members of Congress to withdraw approval of a $625,000 lease of a luxury suite requested by the city’s elected mayor. At the end of his term, Brimmer was succeeded by Alice Rivlin. Brimmer returned to his consulting and scholarly role, proud that he had, in his view, resisted the politicization of important economic and management issues facing the District of Columbia.

A pioneering economist, Brimmer was elected to the Washington Academy of Sciences in 1991 and has held leading elected roles in the American Economics Association, the Eastern Economics Association, and the North American Economics and Finance Association. He has served as an economics professor at Michigan State University, the Wharton School of Finance, and Harvard University, and holds a faculty position as the Wilmer D. Barrett Professor of Economics at the University of Massachusetts, Amherst. Brimmer has also been a member of the Black Enterprise Board of Economists and the Board of Overseers of Harvard University, and he continues to serve as chairman of the Tuskegee University Board of Trustees.

Brimmer’s scholarly interests have focused on monetary issues (see, e.g., Brimmer 1986, 1989, 1993, 1998) and the economic costs to society of racial discrimination (Brimmer 1973, 1995, 2000). Brimmer has long been known for his rigorous mentorship of promising young economists, especially African American scholars. He has brought many of them into his firm, where they have absorbed the critical role of rigorous evaluation of data in advancing their professional economics careers.

No stranger to the private sector, Brimmer’s firm has provided expert economic analysis and testimony for many of the nation’s leading corporations. He has held board positions in such companies as DuPont, Gannett, United Airlines, BlackRock Mutual Funds, and Bank of America. He remains a leading force in the economics profession and corporate America.

BROWN V. BOARD OF EDUCATION, 1954

Legal segregation under “Jim Crow” was a social system that whites developed after the abolition of slavery. Jim Crow’s primary function was to continue the social system of servitude, the racial caste hierarchy, and the economic control of African Americans. After 1896 all aspects of public accommodations, such as transportation, schools, hotels, and parks, were legally segregated in the United States. The legal segregation laws declared that African Americans could not vote, testify against whites, or serve on juries and could attend only segregated schools, orphanages, and hospitals. According to Joe Feagin, “The legal and informal Jim Crow practices meant racial subordination and an imposed badge of degradation on all African Americans in many areas of the United States” (Feagin 2006, p. 123).

In southern states and some northern states legal segregation operated like the system of slavery it replaced. Segregated government agencies exercised extreme control over every aspect of the lives of African Americans. Exploitation and oppression were enshrined by racial violence and discrimination in foundational legal, economic, and social institutions. Numerous challenges to segregated public schools were made before *Brown v. Board of Education* (1954) ended up in the Supreme Court. Peter Irons notes that the first challenge to segregated public schools began in “1849 with a lawsuit filed in Boston by Benjamin Roberts, after his five-year-old daughter, Sarah, was turned away from the primary school nearest her home on the ground of her being a colored person” (Irons 2002, p. ix). The court decided it was best that she continue to attend a segregated school. This Massachusetts Supreme Judicial Court decision preceded the landmark 1896 Supreme Court case of Homer Plessy, an African American man, who refused to sit in the “colored” section on a train, which reinforced local U.S. segregation laws. The decision in *Plessy v. Ferguson* (1896) paved the way for segregation by affirming that separate facilities for blacks and whites could be “separate but equal,” including

racially segregated public schools. The U.S. Constitution and federal court decisions created contemporary forms of the racist institutions functioning in the early twenty-first century.

According to Derrick Bell (2004), in the years leading up to the Roberts and Brown cases, there were pressures from leaders and protestors in the black civil rights movement to end legal segregation. Using a strategy that focused on exposing the actual racial inequality that existed in educational institutions, the National Association for the Advancement of Colored People (NAACP) attorneys Thurgood Marshall and Charles Houston had successfully litigated several cases that led to desegregation in graduate schools. These successes were the inspiration that led them to attempt to dismantle all official segregation in the educational system by arguing that racially segregated schools could never be equal. Marshall combined several cases from states in which racially segregated education was mandated by law, and these cases led to the Supreme Court decision in Brown v. Board of Education of Topeka, Kansas (1954) (Kluger 1951 in Kansas, 1951 in Delaware, 1951 in South Carolina, 1951 in Virginia, and 1951 in the District of Columbia. Even though Brown was a class-action suit, Oliver L. Brown, the father of the third-grader Linda Brown, was named as the first plaintiff in the case. Several attorneys were instrumental in the successful litigation of the case, including Robert L. Carter, Marshall, Spottswood W. Robinson, Houston, Charles S. Scott, Louis L. Redding, Charles Bledsoe, Jack Greenberg, George E. C. Hayes, James M. Nabrit, Harold P. Boulware, Oliver W. Hill, and George M. Johnson. The NAACP Legal Defense Fund worked with scholars such as John A. Davis, Kenneth Clark, John Hope Franklin, and C. Vann Woodward to formulate a strong argument against the “separate-but-equal” doctrine.

In 1954 the landmark decision in Brown overturned the infamous “separate-but-equal” doctrine of Plessy v. Ferguson. The decision was based on the tireless work of African American men, women, and children, including members of the NAACP. Irons notes that once parents of African American children in South Carolina, Virginia, the District of Columbia, Delaware, and Kansas bravely challenged legal segregation in public schools, at great personal risk to themselves and their families, “the Supreme Court finally agreed to decide whether school segregation violated the Constitution’s promise that every American—black or white—will receive the equal protection of the laws” (Irons 2002, p. xi).

THE IMPACT OF BROWN V. BOARD OF EDUCATION
At the center of the Brown v. Board of Education 347 U.S. 483, 495 decision are the words of Chief Justice Earl Warren: “We conclude that in the field of public education ‘separate but equal’ has no place. Separate educational facilities are inherently unequal. Therefore, we hold that the plaintiffs and others similarly situated for whom the actions have brought are, by reason of the segregation complained of, deprived of the equal protection of laws guaranteed by the Fourteenth Amendment” (Feagin 2004, p. 68).

Warren specifically focused and based his decision to end school segregation on the social science research of Clark, who showed that when given a choice, black children viewed white dolls as superior to black dolls. Fundamentally the finding of the Clark research project showed that there was deep psychological damage done to the psyche of black children who were forced to attend segregated schools. The Brown decision impacted school systems and changed American institutions forever. It focused on the public school systems, but its effects reached far beyond the educational institutions. According to Bell, for months following the Brown decision, African Americans participated in organized acts of resistance against other public facilities that were segregated, such as buses and restaurants. The elected white officials of local communities refused to desegregate public facilities, and the violent white responses to peaceful protestors were televised regularly for the entire world to witness. “In addition to publications and the Voice of America broadcasts, the government encouraged and often sponsored Black leaders to travel to foreign countries and convey positive reports about race relations” (Bell 2004, pp. 60–61).

The United States was painfully cognizant of the fact that foreign countries such as Russia were utilizing the heightened racial violence to encourage African Americans to join Communist forces against the country that was denying them their civil rights. Ironically, an unforeseen benefit of the Brown decision was that it mobilized ordinary white citizens, who were horrified by the display on television of brutal attacks against peaceful black civil rights protestors—in most instances women and children—and who joined in public resistance against segregation.

THE CIVIL RIGHTS MOVEMENT
James Patterson (2001) points out that African American men and women who were involved in the civil rights
movement were inspired by the 1954 Brown decision. With the support of liberal whites, African Americans began to fight harder for their civil rights in hopes that legal segregation would finally come to an end. After the Brown decision, African Americans organized sit-ins, boycotts, and demonstrations to end legal segregation. “The civil rights movement was heroic… it inspired even higher expectations than Brown had in 1954” (Patterson 2001, p. xxi). Bell affirms this point: “Brown was the primary force and provided a vital inspirational spark in the post–World War II civil rights movement. Defenders maintain Brown served as an important encouragement for the Montgomery bus boycotters, and that it served as a key symbol of cultural advancement for the nation” (Bell 2004, p. 130).

**BROWN V. BOARD OF EDUCATION REVISITED**

Bell notes that Warren used extremely ambiguous language in his ruling, stating that because of the “wide applicability of this decision, and because of the great variety of local conditions, the formulation of decrees in these cases present problems of considerable complexity” (Bell 2004, p. 18). With these words, the Court postponed ordering any immediate action and ordered the plaintiffs to return to court later to address the issue of implementation.

Consequently the 1954 Brown decision had to be revisited one year later. But even after the courts revisited the issue of implementation, the Supreme Court never provided a specific legal remedy for the desegregation of schools. White southerners objected to the ruling of the Supreme Court and violently resisted the integration of the public school system. Furthermore the consensus in the local courts and among the general white public was that school desegregation could not be achieved. The Supreme Court faced resistance from local legislative and executive levels of government. Seemingly to the threat of mass resistance to its ruling in Brown, the Supreme Court in the Brown II decision issued an extremely vague directive holding that the implementation of desegregation plans must be conducted “with all deliberate speed.”

**IS SEPARATE-BUT-EQUAL BEST?**

In 1935 W. E. B. Du Bois expressed grave concerns about the possible outcomes of black children going to white schools where “white children, white teachers, and white parents despised and resented the dark child … and literally rendered its life a living hell” (Du Bois 1935, p. 330). There was no consensus in the African American community about how to proceed with ensuring that their children had schools and resources that were equal to those of white children. “A separate Negro school, where children are treated like human beings, trained by teachers of their own race, who know what it means to be black … is infinitely better than making our boys and girls doormats to be spit and trampled upon and lied to by ignorant social climbers whose sole claim to superiority is ability to kick ‘niggers’ when they are down” (Du Bois 1935, p. 335).

African American community leaders, parents, and the NAACP worried about the future of their teachers, schools, and universities, and they initially fought to ensure that their institutions were equal to white schools (Patterson 2001). However, in 1950, “after much debate within the NAACP … Marshall [dared] to demand the demolition of Jim Crow in the schools” (Patterson 2001, p. 7).

There have been numerous discussions among scholars who question the success of school integration, the possibility of Marshall and his attorneys fighting for “separate-but-equal” instead of fighting for school integration, and the possible outcomes for African American children. Many parents who attended integrated schools feel positively about the benefits they received and feel good about their children attending integrated schools. The lives of millions of Americans, white and black, have been profoundly influenced by the Brown decision. The failure of the federal and state courts to preserve the gains since Brown v. Board of Education is as deeply troubling as the false notion that segregated schools are more beneficial for children (Boger and Orfield 2005).

**THE RESEGREGATION OF SCHOOLS**

In the early twenty-first century public schools are more racially segregated. The Harvard Civil Rights Project (2006) reports that more than 70 percent of African American students attend public schools that are overwhelmingly nonwhite. There have been significant challenges against affirmative action in federal and state courts. According to Gary Orfield and Chungmei Lee of the Harvard Civil Rights Project:

Since the Supreme Court authorized a return to segregated neighborhood schools in 1991 [Board of Education of Oklahoma City v. Dowell (1991)], the percentage of black students attending majority nonwhite schools increased in all regions from 66 percent in 1991 to 73 percent in 2003–2004…. Over the twelve-year period, the percent of Southern black students in majority non-white schools rose from 61 percent to 71 percent, and the percent of black students in such schools grew from 59 to 69 percent in the Border States. (Orfield and Lee 2006, pp. 9–10)

In 2006 the Supreme Court agreed to hear two cases, Parents Involved in Community Schools v. Seattle School District and Meredith v. Jefferson County Board of...
Education. Based on the Supreme Court’s decision, these cases could overturn Brown. The two cases focus on the right of public schools to decide, in their efforts to promote diversity, where children should go to school based on their race. The white parents in both cases want their children to go to their neighborhood schools. In response to the Supreme Court’s agreement to hear these cases, over 500 social scientists signed a statement urging the Supreme Court to allow American public schools to maintain their ongoing efforts to diversify public schools. Crystal Meredith, the mother of one of the students and the person who filed the Meredith v. Jefferson County Board of Education lawsuit, thinks that a policy that color codes any child denigrates and damages that child’s self-esteem (Benac 2006). The issue of self-esteem, self-worth, and feeling inferior was a central part of the doll research conducted by Clark that was instrumental in the 1954 Supreme Court decision.

Margaret Beale Spencer (1982, 1984), however, criticized Clark and his doll studies research. She conducted extensive research into the relationship between identity and the self-esteem of African American children. Her findings indicate that even though “preschoolers show majority group racial attitudes[,] eighty percent of the sample obtained positive self-concept scores, while demonstrating pro-white biased cultural values on a racial attitude and preference measure” (Spencer 1984, p. 440). Therefore the children in the Clark doll study who chose the white doll were not necessarily demonstrating that their self-esteem was damaged or that they felt inferior because they picked the white doll. Spencer felt that black children chose the white doll because they knew it was valued by society. “Even the Clarks found that seven-year old black children had largely shifted in preference behavior; they more frequently preferred the black dolls” (Harpalani 2004, p. 6).

In the 1940s some scholars criticized the implementation of Clark’s test and the difference in the aesthetics of the dolls. Since black dolls were difficult if not impossible to find in the 1940s, the white doll was more aesthetically appealing and thus one of the reasons black children picked it (Harpalani 2004). However, in 2005 the high school student Kiri Davis created a video, A Girl like Me, that demonstrated that young African American children are still choosing the white doll over the black doll, even though both dolls are aesthetically similar. Indeed there was not a consensus in the African American community about what to do in the 1950s, and there is not a consensus in the early twenty-first century about the success of Brown v. Board of Education in assuring quality education for black children.

Plessy v. Ferguson, 163 U.S. 537. 1896.

BROWN V. BOARD OF EDUCATION, 1955

The original intent of the 1954 Supreme Court decision in Brown v. Board of Education of Topeka was to dismantle the separate-but-equal policy in American public schools. Joe Feagin (2004, p. 68) argues that the language used by Chief Justice Earl Warren (1891–1974), who wrote the Brown opinion, intentionally focused only on public schools: “in the field of public education, the doctrine of ‘separate but equal’ has no place. Separate educational facilities are inherently unequal.” However, the landmark Brown decision did not put an end to segregation in public schools due to the hostile response the decision received from white elites.

Derrick Bell (2004, p. 18) argues that Warren’s use of extremely ambiguous language in his opinion hindered the implementation of desegregation. Specifically, Warren stated that “because of the wide applicability of this decision and because of the great variety of local conditions, the formulation of decrees in these cases presents problems of considerable complexity.” With these words, the Supreme Court postponed any immediate action and ordered the plaintiffs to return to court at a later date to address the issue of implementation.

Consequently, the 1954 Brown decision had to be revisited one year later in the Brown II case, which specifically addressed the issue of remedying racial segregation in American educational facilities. White southerners objected to the Supreme Court’s 1954 ruling, and openly expressed racist sentiment, insisting that they had no intention of integrating the public school system. Furthermore, the consensus among local courts and the white public generally was that school desegregation could not be achieved. The Supreme Court faced outright resistance from state and local branches of government and from lower courts. With this social backdrop, the Court heard legal arguments in 1955 concerning the issue of implementation, and issued the Brown II decision.

According to Bell:

The Court expected a prompt and reasonable start toward full compliance, with defendants carrying the burden of showing that requests for additional time were necessary in the public interest and consistent with good faith compliance at the … earliest practicable date. The court returned the cases to the district courts with the admonition that orders and decrees be entered to admit plaintiffs to public schools on a racially nondiscriminatory basis, “with all deliberate speed.” (Bell 2004, p. 18)

Bell suggests that the Court, in using such weak language as “all deliberate speed,” confirmed that its earlier Brown decision was “more symbolic than real” (2004, p. 19). The phrase “with all deliberate speed” was met with a wide range of responses. As Paul Finkelman points out, “Brown II might have been more forceful and direct. In hindsight we might argue that there should have been more emphasis on speed and less on deliberate.” (2004, p. 36).

Bell describes how federal judge J. Harvie Wilkinson III, “two decades after Brown, offered practical details why Brown II was a mistake.… The enormous discretion of the trial judge in interpreting such language as all ‘deliberate speed’ and ‘prompt and reasonable start’ made his personal role painfully obvious” (2004, p. 19). Judges who wanted to implement desegregation were often met with violent opposition from local whites when they used the words of the Supreme Court. Mindful of the history of racial violence against African Americans in the South, these judges cautiously phrased how the implementation of school desegregation would take place to avoid a violent backlash against African American communities. Furthermore, the failure of the Court to delineate a specific remedy for school desegregation allowed judges who favored racial segregation the means to stall, thus perpetuating segregation in education (Kluger 2004).

In the face of massive resistance from white southerners and from southern courts and legislatures, it took nearly twenty years for the United States to begin large-scale implementation of the Brown decision (Feagin 2004). Today, although racial segregation in schools can no longer be legally imposed, many American schools from kindergarten through twelfth grade remain racially segregated, and in some regions even more segregated than they were before Brown. Education scholars have suggested that this segregation is largely the result of the successful stalling techniques employed in the South, combined with de facto racism in the North, all of which was facilitated by the “all deliberate speed” phrasing of the Supreme Court in 1955 (Orfield and Eaton 1997).

BUBBLES
Bubbles occur when there is excessive investment in financial assets, such as stocks, or in real assets, such as housing. The bubble “burst” when the value of the investment plummets. The value of the investment may plummet for several reasons, including (1) investors realizing that they previously had overvalued the investment, resulting in a massive selling of the investment, and/or (2) the price of what the investment produces falls.

One of the most famous speculative bubbles in history is Dutch Tulipmania (1634–1638), which involved people mortgaging their homes and industries to buy tulip bulbs, which they expected to resell at higher and higher prices. These expectations were based on past increases in prices. In early 1637 prices for some bulbs fell from a peak of several times a typical person’s annual income to almost nothing. The Mississippi Bubble (1719–1720) and the South Sea Bubble (1720) involved the taking over of part of (respectively) France’s and England’s national debts by powerful trading monopolies. Expected monopoly profits from expanding trade drove these bubbles. When people lost faith in those monopolies, the value of their stocks plummeted. The U.S. stock market enjoyed spectacular growth during the 1920s, and people hoping to get rich through the stock market used ever increasing amounts of credit to buy more stocks. The bursting of this stock market bubble in 1929 ushered in the Great Depression. Likewise, the bursting of the Japanese bubble in the 1980s ushered in the worst recession that Japan had suffered since World War II. The Japanese bubble was driven partially by Japanese companies using the money from selling stocks for speculative purposes rather than to produce goods and services that could be sold to the public.

Although Albert Frederick Mummery and John Atkinson Hobson only briefly mention “bubble companies” in The Physiology of Industry (1889) 1989, p. 140), their book provides one of the earliest analyses of what causes excessive investment (bubbles). They argue that the ultimate goal of investment is to produce goods for consumption. If there is no one to consume what the investment produces, then there is no ultimate value gained by investing. A bubble occurs when excessive savings leads to excessive investment that causes excessive production of goods that will not be bought due to insufficient consumption. If one person increases his or her savings, then others must increase their consumption in order to make the first person’s savings valuable. If everyone saves more, then the goods produced by using the increased savings will not sell, making the increased savings worthless. According to Mummery and Hobson, excessive investment is synonymous with underconsumption. To produce sustainable growth, a correct mix must be found between savings, which is needed to finance investment, and consumption, which is needed to buy what the investment produces.

A global perspective can be added to the above analysis by noting that a correct mix of savings and consumption needs to be found on an international level. In a globalized world, countries with excess savings can export their extra savings to countries with excess consumption. One way to export savings is by fixing the exchange rate below its true value to another currency (such as the U.S. dollar), thereby encouraging exports and discouraging imports and thus lowering national savings.

Because bubbles involve “excessive” investment, they logically involve people making mistakes. These mistakes can be based on overreacting, following the herd (fads), decision making by inexperienced traders, viewing investments as a gamble (and enjoying the gambling), or basing
future expectations solely on performance in the recent past. However, contemporary social science is built on an assumption of “rationality,” and the above explanations imply that people make “irrational” mistakes. Thus, many theorists either deny that bubbles occur, or they try to find a rational basis for bubbles.

One explanation that denies that bubbles occur is based on the premise that asset markets adjust more quickly than goods markets. Because of this, a shock in the goods markets can create what appears to be an exaggerated reaction (bubble) in the asset market; however, contrary to appearances, these reactions actually involve the entire system trying to achieve a new equilibrium as quickly as possible. Similar models have been built based on capital, money, and cash-in-advance constraints. Taking a different tack, some explanations hold that high uncertainty about the future productivity of a new technology can cause what looks like a bubble, but that it will go away once the uncertainty is eliminated.

Some explanations that attempt to find a rational basis for bubbles are based on different investors having different beliefs (or information) and on short-selling constraints. Simon Gilchrist, Charles P. Himmelberg, and Gur Huberman show that, under these conditions, firms can issue new shares at inflated prices (2005). By so doing they reduce the cost of capital and increase real investment. Furthermore, they show that even large bubbles are not eliminated in equilibrium. Another group of theories argue that the “results” of bubbles may be “rational” due to the bubbles causing dynamically inefficient states (states with excess investment) to become more efficient (i.e., to reduce their excess investment).

Despite this last group of theories, most experts agree that it is best to avoid bubbles. The chairman of the central banks of the United States and Japan in the 1990s (Alan Greenspan and Yasushi Mieno, respectively) both emphasized reducing speculative bubbles. One way to reduce the chance of speculative bubbles is to warn investors of excessive investment; Greenspan is well known for repeatedly condemning “irrational exuberance” in the U.S. stock market in the 1990s. Other policy responses are to increase taxes on investment and, for countries with excess investment, to promote consumption. Because the rich tend to invest more than the poor and the poor tend to consume more than the rich, policies that create a more equitable income distribution help.

To the extent that some speculative bubbles are based on incomplete or misleading information, the government can play a role in improving information. Furthermore, the punishments should be severe for corporate leaders who are found guilty of misleading investors, and insider trading should be prohibited because it gives insiders an incentive to create a speculative bubble and then exit right before the bubble bursts.

**BUDDHA**

Though often used in a general sense to identify any individual who has achieved enlightenment without the aid of others, the term *Buddha* usually denotes the historical founder of Buddhism, Siddhārtha Gautama. Scholars generally deem Gautama a historical figure who passed along to his followers the foundations of Buddhist philosophy and practice. Frequently referred to as “the Buddha,” or the “Enlightened One,” most Buddhists believe Gautama to be the Buddha for this age (though there have been numerous buddhas throughout history). Accurately reconstructing the precise details of the Buddha’s life and teaching, however, proves difficult. The first biographies of his life did not appear until centuries after his death and it is often impossible to ascertain exactly where the biographies reconstruct the Buddha’s life according to ideal patterns as opposed to historical realities.

**LIFE**

Conventionally, the Buddha was believed to have lived circa 560–480 BCE, though more-recent scholarship suggests the later dates of circa 485–405 BCE. Born in northeastern India (present-day Nepal), Gautama’s father was king of the city of Kapilavastu. Just prior to his birth, Gautama’s biographers hold that Gautama’s mother dreamed of a white elephant coming into her womb; this
in turn led soothsayers to predict Gautama’s future as a
buddha. Prepared throughout his previous lives for this
his final reincarnation, Gautama could walk and talk
immediately following his birth. Throughout his youth,
however, Gautama’s father, Śuddhodana, sought to guard
him against suffering and prepared Gautama to succeed
him as king. Gautama also married during this period
and had a son, Rāhula (according to some traditions Rāhula
[literally “fetter”] was not born until the day Gautama
achieved enlightenment).

At age twenty-nine, however, Gautama’s life pro-
foundly changed when he ventured outside the palace and
encountered “four signs”: an old man, a sick person, a
corpses, and a mendicant (Buddhist sources indicate that
the gods orchestrated these events). Troubled by what he
saw, Gautama then took on the life of an ascetic for the
next several years and searched for an answer to the suffer-
ing he had encountered. In his search for enlightenment,
Gautama excelled in meditation and ascetism (at one
point it was said that he lived off a daily ration of one
pea). Two teachers, Udraka Rāmaputra and Alāra Kālāma,
guided him during this period. Gautama eventually
rejected the positions of his mentors, though, and con-
cluded that strict self-denial did not free an individual
from suffering.

According to Gautama’s biographers, six years after
leaving the palace he finally experienced enlightenment.
One night he sat under a bodhi tree determined not to
leave until he found an answer to the perennial problems
of suffering and death. A period of temptation ensued as
Mara, the god of desire, assailed him through various
means. Gautama resisted these assaults, however, and
meditated throughout the night. By dawn, Gautama’s
meditation culminated in a breakthrough. Though some
traditions differ as to the exact nature of his enlighten-
ment that night, the biographers agree that Gautama
achieved the status of a buddha; he eliminated the igno-
rance that trapped individuals in the suffering (duḥkha)
associated with the endless cycle of reincarnation.

TEACHINGS

Following this experience, the Buddha’s biographers indi-
cate that he basked in his experience for several weeks and
stayed near the tree; soon thereafter he preached his first
sermon at Deer Park in Sarnath, passing along to others
his insight into the dharma (the truth). This first sermon
is often referred to as the “first turning of the wheel of
dharma.” Though it is important to note that many of the
Buddha’s teachings reflect the influence of Hinduism, the
Buddha thoroughly modified various Hindu concepts and
did not embrace the Hindu caste system. The theme of his
teaching revolved around the Four Noble Truths. The first
Noble Truth stipulated the reality of suffering. Put simply,
suffering persists throughout all the various stages of life.
The second Noble Truth indicated that desire (tṛṣṇā) origi-
nated from ignorance (avidyā) and inevitably caused suf-
ferring. According to the Buddha, humans mistakenly
posit the existence of an autonomous, permanent self
(ātman). As such, they inevitably experience suffering as
they try to maintain a permanent hold on things that are
constantly changing and impermanent. Instead, the
Buddha’s teachings advanced the doctrine of “no-self” and
insisted on the impermanence of all things. The third
Noble Truth, the cessation of suffering (nirvāṇa, literally
“blowing out”), claimed it was possible to eliminate desire
and ignorance and free an individual from suffering.
Finally, the fourth Noble Truth pointed to the path that
brings about the cessation of suffering, often referred to as
the Eightfold Path. The path includes (1) right view, (2)
right intention, (3) right speech, (4) right conduct, (5)
right livelihood, (6) right effort, (7) right mindfulness,
and (8) right concentration. This “Middle Path” avoids
both the extreme of self-denial and the extreme of self-
indulgence, and leads an individual to recognize the
impermanence of all things.

Often, the different parts of the Eightfold Path are
grouped under three main headings: moral precepts, con-
centration, and wisdom. The moral precepts (śīla) usually
include basic prohibitions against killing, stealing, lying,
sexual promiscuity, and intoxication (these are commonly
accepted by most Buddhists, though monks and nuns
usually adhere to more stringent guidelines). Concentra-
tion (samādhi) involves various forms of meditation that
differ among Buddhist traditions. Generally, however,
Buddhist meditation requires careful control of the
process of breathing and discipline of the mind. Finally,
wisdom (prajñā) reflects the necessary insights required to
eliminate desire and ignorance and achieve enlightenment.

The Buddha would continue to teach throughout
northeastern India for the next forty-five years of his life,
and he soon attracted a cadre of followers. Many of his
biographies say relatively little about this period of the
Buddha’s life. Tradition indicates that the Buddha formed
